Original Research Article

EVALUATION OF ANTIMICROBIAL ACTIVITIES OF FRACTIONS OF PLANT PARTS OF *Pterocarpus santalinoides*

ABSTRACT

Aims: The study aims to investigate the antimicrobial activities of the leaves, seeds, bark and root of *Pterocarpus santalinoides* plant.
Study Design: Agar well diffusion and Agar well dilution methods were used to test the preliminary antimicrobial and minimum inhibitory/bactericidal/fungicidal concentrations respectively of *Pterocarpus santalinoides* plants.
Place and Duration of Study: Department of Pharmaceutical Microbiology and Biotechnology, Faculty of Pharmaceutical Sciences, Nnamdi Azikiwe University, Agulu Campus, Nigeria, between February – October, 2017.
Methodology: Primary extraction and fractionation was done on the plant parts with methanol, butanol, ethyl acetate and n-hexane. Agar diffusion method for the primary antimicrobial screening on Muller-Hinton agar (Bacteria) and Sabouraud dextrose agar (Fungi) were used to test the antimicrobial activities of the sixteen (16) samples on some microorganisms; *Salmonella typhi*, *Escherichia coli*, *Candida albicans*, *Aspergillus niger*, *Microsporon canis* and *Trichophyton rubrum.* The minimum Inhibitory concentration (MIC), minimum bactericidal/fungicidal concentration (MBC/MFC) and percentage inhibition diameter growth (PIDG) of the samples that gave activity were also evaluated.
Results: Twelve (12) samples showed inhibitory activity on at least one or more of the test organisms. The MIC range observed for the extracts and fractions that gave activity was 12.5 – 100 mg/ml. The n-hexane fraction of the plant root gave the best value of 12.5 mg/ml against *Microsporon canis.* The best MBC/MFC value of 25 mg/ml was observed with the ethyl acetate fraction of the bark (against *E. coli* and *M. canis*) and the n-hexane fraction of the root (against *M.* canis). The result showed *S. typhi* to be the most sensitive organism to the metabolites of *P. santalinoides.* Extended spectrum activity was observed with the ethyl acetate fraction of the bark against three (3) of the test organisms; *S. typhi*, *E. coli* and *M. canis.* The determination of PIDG values for the test organisms against the plants' extracts/fractions showed that crude methanol extract (28.57%) and ethyl-acetate fraction (0.14%) of the leaves, Butanol fraction (0.14%) of the root (all against *Salmonella typhi*) were the most potent test samples.
Conclusion: The result indicates that the plants may have potential medicinal values and suggests its use in traditional medicine.

Keywords: Pterocarpus santalinoides; Antimicrobial; Methanol; n-hexane; Ethyl acetate; Butanol.

1. INTRODUCTION

Medicinal plants have been of great value to mankind. The use of herbs as complementary and alternative medicine has increased dramatically in the last 20 – 25 years [1]. Higher plants have been used for centuries as remedies for human diseases [2, 3]. Different plant parts have also been used for various forms of diseases and infections. This has encouraged research into screening of plants for antibacterial and antifungal activities [4].

The increased material worth of medical treatment and their strong physiological or chemical effects, contribute to the reason why individuals make use of herbal therapy. The increasing demand of plant extracts used in the cosmetic, food and pharmaceutical industries suggests that systematic studies of medicinal plants are very important in order to find active compounds and their use as a medicine for curing various diseases.

UNDER PEER REVIEW

Pterocarpus santalinoides is a tree 9 - 12 m tall, 1 m diameter at breast height (DBH), with low straggling branches. Bark thin and flaking in small patches, slash yellowish-white exuding drops of red gum [5]. It is a shade tolerant tree commonly found along riverine forests in Africa and tropical South America [6].

In Nigeria many indigenous plants including *Pterocarpus Santalinoides* are used as food or medicine. The tender leaves are used as vegetable in soup preparing, while the stem bark is used in making pepper soup. *Pterocarpus santalinoides* is a plant believed to possess potent antibacterial properties in ethno medicine. The plants are used in treating rheumatism, diarrhea, dysentery, cough, ashma, diabetes, malaria, elephantiasis, cold and others [7]. The use of the plant leaves in treating skin disease such as eczema, candidiasis, and acne have been reported [8]. The use of the concoction made from its root in treating asthmatic patients have also been reported [9]. It is also used in treating diarrhea which is a major cause of death as it has a proven anti enteropoling activity in traditional medicine [10].

This research is aimed at investigating the antimicrobial activities of various parts of the plant against some indicative organisms implicated in their traditional use.

2. MATERIALS AND METHODS

2.1 Plants Materials

The fresh leaves, seeds, bark and roots of *Pterocarpus santalinoides* were sourced in September 2016 from Okofia - Otolo Nnewi, Anambra state, Nigeria, latitude $5^0$58'48.86'' and longitude $6^0$54'30.78''. They were identified and authenticated by a Curator in the Department of Pharmacognosy, Faculty of Pharmaceutical Sciences, Nnamdi Azikiwe University, Nigeria.

2.2 Culture Media and Reagents

Culture media used were Nutrient Broth, Mueller-Hinton agar (Oxoid Limited, England) and Sabouraud dextrose agar (Titan Biotech, India). Culture media were prepared according to the instructions of the manufacturers.

Reagents used include McFarland 0.5 turbidity standard (prepared from Barium chloride, Sulfuric acid and water), sodium hypochlorite solution and dimethyl sulphoxide (Triveni Chemicals, India).

~~2.3 Equipment~~

~~Equitron partially automatic autoclave (Medica Instrument Manufacturing CO., India), hot air oven (Genlab, UK), incubator (Genlab, UK), electronic weighing balance (Ohaus Corp., USA).~~

~~2.4~~2.3 Microbial Test Organisms

The microorganisms used in this study were two bacteria isolates (*Escherichia coli* and *Salmonella typhi*) stored at 4 – 8 ºC in Mueller-Hinton Agar slants and four fungi isolates (*Candida albicans*, *Aspergillus niger*, *Trichophyton rubrum* and *Microsporon canis*). These were clinical isolates previously purified and standardized to McFarland. Their susceptibility to commonly used antibiotics was already established. The isolates were obtained from the Department of Pharmaceutical Microbiology & Biotechnology, Nnamdi Azikiwe University, Awka, Nigeria.

~~2.5~~2.4 Extraction of Plant Materials

The different plant parts of *Pterocarpus santalinoides* were prepared using the method of [11]. They were dried at room temperature (25 ^oC), grounded into a fine powder using laboratory grinding mill and stored in a cool and dry place. Total extraction of each plant materials were prepared by mixing with solvent (methanol) in the ratio of 1:10 (plant material/solvents) in a cold maceration system. The plant materials

Formatted: Space Before: 0.3 line, After: 0.3 line

Formatted: Font: Not Italic

Comment [GP1]:

UNDER PEER REVIEW

were soaked in 1000 ml solvent in conical flasks for 12 hours. The extracts were then filtered using Whatman No. 1 filter paper and solvents removed through evaporation under reduced pressure at 45 °C using a rotary evaporator (Yamato, USA). The extracts were kept in stoppered sample vials at 4 °C until they were used.

~~2.6~~2.5 Fractionation of Crude Methanol Extracts

The crude methanol extracts of the different parts of the plant were fractionated using solvent-solvent method with n-hexane, ethyl acetate and butanol in order of increasing polarity.

~~2.7~~2.6 Percentage Yield Determination

The percentage yield (%, w/w) from all the dried crude methanol extracts was calculated using the formula outlined below:

$$\text{Percentage (\%) yield} = \frac{\text{Weight of extract}}{\text{Weight of dried plant material}} \times 100 \quad \text{.........Equation 1}$$

2.8 Preliminary Antimicrobial Assay

The Preliminary antimicrobial assay for each of the crude extracts and their respective fractions was carried out using the agar well diffusion assay as described by [12]. The antimicrobial activity of the plant parts (i.e. crude extracts and fractions) were tested against standard clinical isolates (two bacteria and four fungi isolates) as listed above. A 0.5 McFarland standard bacterial/fungal suspension of each of the test isolates were prepared and these formed both the bacterial and fungal stock solutions used in the agar well diffusion assays as outlined below.

2.9 Agar Well Diffusion Assay

Briefly, the media, Mueller-Hinton agar, MHA (Oxoid, USA) and Sabouraud dextrose Agar, SDA, were prepared and treated according to the manufacturer's specification. ~~MHA (38 g) and SDA (65 g) respectively were mixed with 1L of sterile distilled water and sterilized at 121 °C for 15 mins~~. The media was allowed to cool to 50 °C and later transferred into 90 mm sterile agar plates and left to set. The sterile MHA and SDA plates were inoculated with the test culture from each of the test suspensions, thereafter, 20 ml of the sterile molten agar cooled to 50 °C was added then to the plate and was rocked clockwise and anti-clockwise to ensure even distribution of the test organism. This was done to obtain uniformity of the inoculums. A sterile cork borer was used to make wells (6 mm in diameter) on each of the MHA and SDA plates respectively. Aliquots of 60 µl of the stock concentration (100 mg/ml) of each extracts and fractions, reconstituted in dimethyl sulphoxide (DMSO) were applied in each of the wells in the culture plates previously seeded with the test organisms. Ciprofloxacin (5 µg) and miconazole (50 µg/ml) served as the positive controls for the bacteria and fungi respectively, while DMSO served as the negative control. The cultures were incubated at 37 °C for 18 - 24 hours for the bacterial plates and 25 – 27 °C for 48 hours for the fungal plates respectively. The antimicrobial potential for each extract and fraction was determined by measuring the zone of inhibition around each well (excluding the diameter of the well). For each extract and fraction, three replicates were conducted against each organism. Each extract and fraction was tested against all the bacterial and fungal isolates.

Comment [GP2]:

Furthermore, based on the recorded activity, the extracts and fractions that showed activity were subjected to minimum inhibitory concentration (MIC) and maximum biocidal concentration (MBC) Determinations.

2.10 Anti-dermatophyte Activity

The anti-dermatophyte activity was conducted using the method as described by [13]. A sterile swab was used to aseptically inoculate each of the fungal suspension (*Trichophyton rubrum and microsporon canis*)

UNDER PEER REVIEW

on the surface of sterilized Sabouraud dextrose agar. The tests were carried out using a stock concentration of 100 mg/ml prepared by dissolving 200 mg of the crude extracts and fractions into 2 ml of DMSO. A well of 6 mm diameter was made in the agar plate then loaded with 60 µl of each of the stock concentration of the crude extracts and fractions of the test samples and incubated at 28 ± 2 °C for 15 - 20 days. The inhibition zone was observed and then recorded in millimeters using a transparent metre rule. The test was conducted in triplicate and results presented as mean. Miconazole 50 µg/ml served as the standard positive control against the *dermatophytic species.*

2.11 Determination of Minimum Inhibitory Concentration (MIC)

The MIC was interpreted as the lowest concentration of the test samples (extracts and fractions) that inhibited visible growth. The MICs of the active samples were determined by agar dilution method as described by [13, 14] for the antimicrobial and anti-dermatophytic activities respectively. The MIC was determined for the micro-organisms that showed reasonable sensitivity to the test crude extracts and fractions. In this test, a stock solution of the crude extracts and fractions (2,000 mg/ml) was made, then 2-fold serial dilution was done to get graded dilutions (1000, 500, 250, 125, and 62.5 mg/ml) of each of the crude extract and fraction. Then 1 ml of each of ~~these concentration~~these concentrations was transferred into a sterile petri dish and properly mixed with 9 ml of molten Mueller-Hinton agar and Sabouraud dextrose agar, then cooled to 45 - 50 ^{o} C. After the mixing was done the final concentrations becomes 100, 50, 25, 12.5, and 6.25 mg/ml respectively. Finally, the different test organisms were streaked on the solidified agar properly labeled and incubated at 37 °C for bacteria and 28 ± 2 °C for fungi. The bacteria where incubated for 18 – 24 hours, while *Candida albicans* and *Aspergillus niger* were incubated for 48 hours and the dermatophytes incubated for 15 - 20 days. Each experiment was performed in triplicate.

2.12 Determination of the Minimal Bactericidal/Fungicidal Concentration of the Crude Extracts and Fractions (MBC)

This is the minimal concentration which kills off the cells in a microbial population. The MBC/MFC is the lowest concentration producing no evidence of growth [14]. It is an extension of the MIC procedure (stated above) carried out. Here, the plates that show no visible growth in the MIC test were selected. Then, they are incubated for 48 more hours. Thereafter, the plates were examined for signs of microbial growth.

2.13 Determination of the Percentage Inhibition Diameter Growth (PIDG)

Following the observation for the antimicrobial evaluation, the percentage inhibition diameter growth (PIDG) values were determined according to the equation as below.

$$\text{PIDG (\%)} = \frac{\text{Diameter of sample} - \text{Diameter of control}}{\text{Diameter of control}} \times 100 \quad \text{………………equation 2}$$

2.14 Data Analysis

The results were expressed as mean. Statistical analysis was carried out using one way analysis of variance (ANOVA) and SPSS (version 20) statistical program. The obtained results were considered significant at P = 0.05.

3. RESULTS

3.1 Extraction, Fractionation and Percentage Yield

Each of the leaves, seeds, barks and roots of *Pterocarpus santalinoides* were extracted with methanol as primary solvent. This yielded four (4) crude methanol extracts of the plant samples. The leaves (8.27 %)

UNDER PEER REVIEW

gave the highest percentage yield as depicted in (Table 1). This was followed by the bark (5.97 %). The least value was observed with the seeds (1.97 %).

The solvent-solvent fractionation of the four (4) crude methanol extract of the plant, *Pterocarpus santalinoides* with n-hexane, ethyl acetate and butanol in their order of increasing polarity gave a total of four (4) fractions each of the three (3) secondary solvents giving a total sample of sixteen ((4) each of the crude methanol extracts, n-hexane, ethyl acetate and butanol fractions respectively) samples.

Table 1: The percentage yield of crude extracts obtained from *Pterocarpus santalinoides*

Plant Parts	Powdered Plant materials (Wt. in g)	Extract weight (g)	Percentage yield (%)
Leaves	546.10	45.15	8.27
Seeds	500.00	9.87	1.97
Barks	450.00	26.87	5.97
Roots	307.89	15.16	4.92

3.2 Antimicrobial Activity of *Pterocarpus sanatalinoides* Extracts and Fractions against the Test Isolates

The antimicrobial activities of the plant extracts and fractions were tested against six (6) pathogenic cultures comprising of two (2) bacteria strains - *Escherichia coli* and *Salmonella typhi,* and four (4) fungi species - *Candida albicans*, *Aspergillus niger*, *Microsporon canis and Trichophyton rubrum*. The IZDs were variable ranging from 2 - 9 mm. Broad spectrum antimicrobial agents (ciprofloxacin and miconazole) were used as a positive control while Dimethylsulfuroxide (DMSO) was used as negative control.

A total of 16 crude methanol extracts and fractions of the plant parts were tested for their antimicrobial activity among which 12 samples showed inhibitory activity on at least one or more of the test pathogenic microorganisms. In contrast, 4 samples (PSL n-hexane, PSB Crude, PSB Butanol, PSB n-hexane) showed no activity against any of the selected microorganism at the tested concentration. The result showed that ethyl acetate fraction of the plant bark (PSB Ethyl acetate) has antimicrobial activity against 3 of the tested organisms (*Salmonella typhi*, *E. coli* and *Microsporon canis*).

The Ciprofloxacin (5 µg/ml) conventional drug used as control was active against the bacterial isolates with mean inhibition zone diameter (IZD) of 7 mm against *S. typhi* and 5 mm against *E. coli*. The Miconazole (50 µg/ml) used as control for fungal isolates was active against all the fungal isolates with mean inhibition zone diameter (IZD) of 18 mm for *Candida albicans* and *Microsporon canis* and 9 mm for *Aspergillus niger* and *Trichophyton rubrum* respectively. This reveals that the tests organisms used in the course of this work were susceptible strains. The DMSO serving as the negative control had no inhibition activity on any of the test organisms. The results of the antimicrobial activity of the plant parts are summarized in Tables 2.

Table 2: Mean Inhibition Zone Diameter (IZD) mm of the preliminary antimicrobial activity of the crude extracts and fractions of *Pterocarpus santalinoides* against some selected clinical isolates.

The comparison of the activity of the extracts and fractions of *Pterocarpus santalinoides* according to the parts showed that the extracts and fractions significantly (p=0.05) inhibited some of the test organisms. For the leaves; the crude methanol extract (PSL Crude) had better antimicrobial activity to the only sensitive organism which is *Salmonella typhi* followed by ethyl acetate fraction (PSL Ethyl acetate) and Butanol fraction (PSL Butanol) respectively. The n-hexane fraction (PSL n-hexane) had no inhibition activity. This result indicates that the active agents in the plant leaves against this organism are chiefly polar compounds. For the Seeds; the ethyl acetate fraction (PSS Ethyl acetate) had the best inhibition activity against *S. typhi* followed by n-hexane (PSS n-hexane) and butanol (PSS Butanol) fractions respectively. The crude methanol extract (PSS Crude) was not active against *S. typhi*, however, was the only sample of the plant seeds active against *E. coli*. No part of the plant seeds has inhibition activity against *C. albicans*, *A. nig r*, *M. canis* and *T. rubrum*. From this result, the phytochemicals in the seeds active against *S. typhi* are mainly non-polar compounds, however, the compounds active against *E. coli* are polar compounds. It also showed that after fractionation of the crude methanol extract (PSS Crude),

UNDER PEER REVIEW

286 the active principles in the seed against *E. coli* was lost, which indicates an antagonistic effect of the
287 fractionation process on the active principles. No part of the bark had inhibition activity on any of the
288 tested organisms except for ethyl acetate fraction (PSB ethyl acetate) which had activity against *S. typhi*,
289 *E. coli* and *M. canis*. This result showed that the active principles in the plant are bipolar compounds. This
290 is logically in accordance to some work done [15] that tested the antimicrobial activities of the ethanol and
291 water extracts of *P. santalinoides* bark against organisms including *S. typhi* and *E. coli*, of which the water
292 extracts (a polar solvent) did not inhibit these test isolates at the concentration used. The ethanol extracts
293 only marginally inhibited the organisms. For the roots, the crude methanol extract (PSR Crude) and the n-
294 hexane fraction (PSR n-hexane) had no activity against *S. typhi*. The butanol fraction (PSR Butanol) had
295 the best activity against *S. typhi*. Only the crude methanol extract (PSR Crude) showed inhibition activity
296 against *E. coli*. The best antimicrobial activity was observed with the n-hexane fraction (PSR n-hexane).

297

298 Comparison of the susceptibility of all the test organisms to the various extracts/fractions of the plant
299 parts, indicated that *Salmonella typhi* appeared to be the most sensitive organism to metabolites from
300 *Pterocarpus santalinoides* with 9 of the extracts/fractions showing inhibitory activity and the best activity
301 was observed with the crude methanol extract of the plant leaves (PSL Crude) were IZD of 8 mm, MIC of
302 50 mg/ml and MBC of 100 mg/ml were recorded. In contrast, *Candida albicans* and *Trichophyton rubrum*
303 were found to be the most resistant organisms where none of the extracts/fraction showed antimicrobial
304 effect at tested concentrations.

305

306 Three samples (PSS Crude, PSB Ethyl acetate and PSR Crude) showed antimicrobial activities against
307 *Escherichia coli* with the best activity observed for crude methanol extract of the plant seed (PSS Crude)
308 where IZD of 5 mm and MIC of 100 mg/ml were record. No part of the plants' leaves extract/fractions had
309 activity against *E. coli*. This is similar to work done by [16], who evaluated the antimicrobial activities of
310 the methanol extracts of the plant leaves against *S. aureaus* and *E coli*, of which *E, coli* showed no
311 activity at all concentrations (up-to a maximum concentration of 50 mg/ml). *Microsporon canis* was
312 inhibited by only two fractions (PSB Ethyl acetate and PSR n-hexane), while *Aspergillus niger* was
313 inhibited by only one fraction (PSR n-hexane).

314

315 The ethyl acetate fraction of the plant bark (PSB Ethyl acetate) showed activities against 3 of the tested
316 isolates producing IZD of 4 mm against *Salmonella typhi*, 3 mm against *Escherichia coli* and 4 mm
317 against *Microsporon canis* showing an extended activity than the other extracts/fractions with activities
318 against 2 Gram negative and 1 fungi isolates. This is similar to a work done by [17], were a broad
319 spectrum activity of the plant bark was reported as was observed in this study. However, the best
320 antifungal activity was observed for n-hexane fraction of the plant root (PSR n-hexane) where an IZD of 2
321 mm against *Aspergillus niger* and 6 mm against *Microsporon canis* were recorded.

322

323 The result of this study showed that the various extracts and fractions of the plant have antimicrobial
324 activity against *Salmonella typhi*. Similarly, [18] reported the activity of this plant to this organism.

325

326 3.3 Minimum Inhibitory Concentration (MIC) and Minimum Bactericidal/Fungicidal 327 Concentration (MBC/MFC) of *Pterocarpus santalinoides* Extracts and Fractions

328

329 The lowest concentration of the extracts and fractions of the plant parts at which no growth of
330 microorganism was observed upon visual observation after incubation was considered the MIC value.
331 The range of MIC of the plants extracts and fractions recorded was 12.5 – 100 mg/ml. The n-hexane
332 fraction of the root gave the lowest MIC value (12.5 mg/ml) against *Microsporon canis*, followed by ethyl
333 acetate fraction of the bark with 25 mg/ml against *E. coli* and *Microsporon canis*.

334

335 The lowest concentration of the extracts and fractions of the plant parts at which no growth of
336 microorganism was observed upon visual observation after further incubation of the MIC plates were
337 recorded as the Minimal Bactericidal Concentration (MBC) for bacteria isolates and Minimum Fungicidal
338 Concentration (MFC) for fungal isolates. This is shown in Table 4. The ethyl acetate fraction of the bark

UNDER PEER REVIEW

339 (PSBE) and the n-hexane fraction of the plant root (PSRn) gave the lowest value (25 mg/ml) against *E.*
340 *coli* and *Microsporon canis* respectively.
341
342 **3.4 Determination of the Percentage Inhibition of Diameter Growth (PIDG)**
343
344 The determination of the PIDG for all the test organisms showed the most potent samples using the
345 samples with higher Inhibition Zone Diameter (IZD) (Table 5) compared to the positive control used (5
346 µg/ml Ciprofloxacin) as threshold/standard.

The best MIC value was observed with n-hexane fraction of the plant root (PSRn) against *Microsporon canis*, followed by ethyl acetate fraction of the plant bark (PKBE) with MIC of 25 mg/ml against *E. coli and Microsporon canis*. The best MBC value was observed with ethyl acetate fraction of the bark (PSBE) and n-hexane fraction of the roots (PSRn) were 25 mg/ml was observed against *E. coli* and *Microsporon canis* respectively.

The Research conducted by [6], on the preliminary phytochemical analysis of methanolic extract of *Pterocarpus santalinoides* leaves showed the presence of alkaloids, anthocyanins, carotenoids, flavonoids, resins, saponins, steroids, terpenoids and tannins, while [19] revealed the presence of leucoanthocyanins, coumarins, flavonoids, mucilage, saponins and tanins. The presence of alkaloids, flavonoids, tannins, saonins, phenolics and cyanogenic glycosides were revealed by [15] in the ethanoloc extracts of the plant stem bark. No study was seen on the phytoconstituents of the plant's seed and root, but relatively will have the compounds as listed above, though environmental factors affects plants phytoconstituents. The antibacterial activities observed with these plant extracts and samples can be attribiuted to these secondary metabolites [15, 20]

UNDER PEER REVIEW

472 The determination of PIDG values for the test organisms against the plant extracts/fractions showed that crude methanol extract (28.57%) and ethyl-acetate fraction (0.14%) of the leaves, Butanol fraction (0.14%) of the root (all against *Salmonella typhi*) were the most potent test samples using the samples that outstrips the positive control used, which was 5µg/mL Ciprofloxacin as the threshold/standard. Additional information from further studies on the mechanism of action of these extracts and fractions might contribute to its usage as an alternative to the conventional antibacterial drugs for the management of *Salmonella typhi* and *E. coli* implicated diseases.

4. CONCLUSION

The study revealed that the various parts of the plant has antibacterial potentials especially organisms implicated in diarrhea as was seen with *S. typhi* and *E. coli*. The plant can be said to have negligible antifungal activities. It also shows that the solvent used for extraction or fractionation can affect the antimicrobial effect of the extracts/fractions. There is need for more studies towards isolation, identification and characterization of the bioactive agents and also test for activities against wilder spectrum of organisms.
