

Perceived Effects of Farmer Participation in Utilization and Conservation of Forest Resources in Otukpo Local Government Area of Benue State

Abstract

This study assessed the perceived effects of farmer participation in utilization and conservation of forest resources in Otukpo Local Government Area of Benue State. Data were collected from 150 farmers randomly selected, using structured questionnaire. The data were analyzed using both descriptive (percentages, frequencies and means) and inferential statistics (multiple linear regression). Result of the analysis indicated a low participation of farmers in forest conservation. The farmers however, had a positive perception on the fact that community participation in forest conservation increases job opportunities ($\bar{x} = 4.65$) and reduces poverty ($\bar{x} = 4.16$). Result of the linear regression analysis revealed that age had a negative (-0.009142 : $p < 0.01$) and significant relationship with farmers' perceived effect of community participation in utilization and conservation of forest resources, while household size (0.0169081 : $p < 0.05$), education (0.0503444 : $p < 0.1$) and farm size (0.1228889 : $p < 0.1$) all had positive and significant relationships with farmers' perceived effects of community participation in utilization and conservation of forest resources. It was concluded that farmers' participation in conservation of the forest was very low. The need for sensitization of the farmers on the importance of participation in forest conservation by all the stakeholders was recommended.

Key words: Perceived effects, farmer, participation, utilization, conservation, forest resources

1. INTRODUCTION

Forests provide products for different uses at households and industrial levels [1]. These products are highly valued worldwide as they play an important role in sustaining the livelihoods of communities living around forest areas [2]. They are important income generating products for local people living close to the forests, contributing significantly to household income, food security, and household healthcare as well as, provision of multiple social and cultural values [3,4]. In the developing nations, forest products are considered as safety net that fills the gaps due to a shortfall in agricultural production or other forms of emergencies [5,6,7].

Communities living close to protected areas in developing countries have historically depended on forest resources for their livelihoods' sustenance especially in times of hardship due to a shortfall in agricultural production and other forms of emergencies [8,9]. For most households in these communities, forests remain a bank of resources from which they derive additional income through consumption and sales of forest products [10,11,12]. Thus, sustainable extraction of forest products can be promoted as one of the rural development and biodiversity conservation strategies in forest rich areas [11]. In Nigeria, the problem of high population density coupled with limited off-farm income generating activities in rural areas, households adjacent to forests commonly rely on forest resources to supplement their household income [13].

Community participation in the conservation of forest resources can make a significant contribution to poverty reduction in the local community where the forests are located. The justification for community participation in natural resources conservation as viewed by International Union for conservation of Nature [14] provides that human culture must be based on a respect for nature and that the present generation have a social responsibility to conserved nature for the welfare of future generation. The view recognizes that mankind is part of nature and that all species have an inherent right to exist regardless of their materials value to humans [15].

Different studies in the Community Forestry show that it is possible to reduce poverty from forest by securing resources for poor, increasing the availability of a range of resources and providing potential for income generation activities (IGAs) [16,17,18]. The need for communities to invest in forest

58 resources conservation and to reduce the effect of environmental degradation is indisputable in
59 Nigeria and particularly in Otupko Local Government Area of Benue State. The people in the study
60 area are highly dependent on forest ecosystem for its diverse and abundant Natural wildlife, land,
61 food and water resources. Therefore, this study was conducted to assess the perceived effects of
62 farmer participation in utilization and conservation of forest resources in Otukpo Local Government
63 Area of Benue State. It specifically described the farmers' socioeconomic characteristics, identify the
64 benefits derived from or uses of the forest/forest products and determine the farmers' participation in
65 forest conservation. This study also determined the relationship between farmers' socioeconomic
66 characteristics and perceived effects of community participation in utilization and conservation of
67 forest resources.
68

69 2. METHODOLOGY

70
71 This study was conducted in Otukpo Local Government Area (LGA) of Benue State, Nigeria. Otukpo
72 LGA covers an area of 1,269 km². It is bounded to the north by Apa LGA, to the east by Gwer East
73 and Gwer West LGAs, to the south by Obi LGA, to the south-west by Ado LGA, and to the west by
74 Okpokwu and Ohimini LGAs and Kogi State. Otukpo LGA has a population of 261,666 [19]. It has an
75 average temperature of 29°C and is mostly characterized by grassy and flat topography. The LGA
76 witnesses two distinct seasons which are the dry and the rainy seasons with the total precipitation of
77 the area put at an estimated 1550 mm per annum. Otukpo LGA also has a few hills and the area is
78 well forested [20].
79

80 Otukpo Local Government Area was targeted for this study. Four communities, namely Ibaji, Ilaba,
81 Odaubi and Ogobia were purposively selected due to their pronounced use of forests resources.
82 About 3% of the farmers from each of the 4 communities were randomly selected to obtain a total of
83 150 farmers out of about 5000 for the study sample.
84

85 Primary data for this study was obtained through the use of a structured questionnaire administered to
86 the respondents. Data were analyzed using both descriptive (frequencies, percentages and means)
87 and inferential statistics (linear regression analysis). Frequencies, percentages and means were used
88 to describe the socioeconomic characteristics of the farmers and identify the benefits derived from or
89 uses of the forest resources to the farmers. A 5-point Likert-type scale was used to examine the
90 perceived effects of community participation in utilization and conservation of forest resources. Linear
91 regression analysis was used to determine the relationship between farmers' socioeconomic
92 characteristics and perceived effects of community participation in utilization and conservation of
93 forest resources.
94

95 The linear regression model is expressed as:

$$96 Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_7 X_7 + e$$

97
98 Where;

100
101 Y= Farmers' perceived effects of community participation in utilization and conservation of forest
102 resources; X₁ = age, X₂ = sex, X₃= marital status, X₄ = house hold size, X₅= years spent in attaining
103 formal education, X₆ = farming experience, X₇ = annual income from non forest products, β₁ =
104 coefficients to be estimated and e = error term.
105

3. RESULTS AND DISCUSSION

3.1 Socioeconomic characteristics of the farmers

The socioeconomic characteristics studied include age, sex, marital status, educational qualification, household size, farm occupation, non-farm occupation, annual income from non forest products and agricultural farm size. Table 1 showed that 44.67% of the respondents were within the age range of 30 – 49 years, 32.0% were within the range of 50 – 69 years, and 23.33% were within 70 years and above. The mean age of 54.91 years indicated that most of the farmers in the study area were relatively young and within their active and productive ages.

Tables 1 also showed that majority (90.00%) of the respondents were males and married (61.30%). This implies that farmers in the study area were predominantly males and married, with family responsibilities. About 48.00% of them had a household size within 1 – 9 members, 39.30% had within 10 – 20 members while 12.70% had within 21– 45 household members. This implies that most of the farmers had more than 9 members in their households. The result indicated that 48.66% of the respondents had 11- 20 years of farming experience, 31.33% had 21 - 30 years and 14.66% had less than 10 years with a mean of about 20 years (Table 1). This implies that most of the farmers had at least 10 years of farming experience.

The result indicated that 31.30% of the respondents had secondary education, 24.70% had primary education, 24.00% had tertiary education and 20.00% had adult education. This implies that 80% of the farmers had formal education. Majority (80.67%) of the respondents had 0.1-1.99 ha of farmland, 16.67% had 2 - 3.89 ha and only 2.67% had more than 3.89 ha farmland. This implies that majority of the farmers had a small farmland. Having small holdings is one of the characteristics attributed to farming and farmers in Nigeria. Majority of the respondents mainly produced either crops (58.00%) or livestock (35.30%). This indicates that crops and livestock production are the major farming activities carried out by the farmers in the study area. Most of the respondents reported that they engaged in other occupations outside farming. Among them were traders (40.00%) and artisans (32.67%) (Table 1). Such occupations are important sources of additional income, thereby improving the farmers' standard of living.

On their estimated annual turnover from forest products, about 31.33% of them had an annual income within ₦300,000 - ₦499,000, 25.33% had less than ₦100,000, 23.33% had within ₦100,000 - ₦299,000, and 20.00% had more than ₦499, 000, annually from the forest products. This implies that majority of the farmers had at least ₦100,000 annually from the forest products (Table 1).

In a study to determine the perceived influence of socio-economic factors of Fadama III farmers on forest resources values in Benue State, Nigeria, [21] reported that majority (83.5%) of the respondents were males and married (100%) with a mean age of 44 years. They added that 46% of the respondents had non-formal education and 43.1% of them earned between ₦401, 000 and ₦800, 000 annually with the mean annual income value of ₦570, 000. The respondents cultivated between 1-3ha (89.0%).

Table 1. Distribution of farmers according to socioeconomic characteristics (n= 150)

Variables	Frequency	Percentage	Mean
Age (years)			
30 – 49	67	44.67	54.92

152

153

154

3.2 Benefits derived from or uses of the forest/forest products

155 Result in Table 2 showed that majority (65.33%) of the respondents reported that the forest
 156 maintained and restored the soil fertility and stability in their lands. About 60.00% of them obtained
 157 both raw materials for harvest and transport equipments and for packing and processing food from
 158 the forest. Other benefits derived from the forest/forest products include provision of raw materials for
 159 crop support (59.33%), provision of raw materials for boats, nets, traps, poles poisons and fuel
 160 woods for fish preservation and for protecting crops such as fencing materials and plant-based
 161 insecticides (58.00%), both raw materials for agricultural implements and crop storage containers
 162 (57.33%), both raw materials for crop marketing equipment and for food stores (56.67%). This implies
 163 that most of the farmers benefitted in several ways from the forest/forest products. It also indicates
 164 the numerous benefits derivable from the forest. Hence, forests should be judiciously utilized and
 165 adequately conserved.

166

167 The World Bank report of 2007, affirmed that approximately 1.7 billion people directly and indirectly
 168 depend on forest products and resources such as honey, firewood, timber, fodder, and fruits for their
 169 livelihood. The report further articulated that various user groups including herdsmen, hunters, and
 170 firewood and pole collectors benefit from exploiting forest resources in different ecosystems [22]. [23]
 171 reported that main benefits from forests through the services forests provided were social, economic
 172 and environmental in nature. Such benefits included among others, provision of woods for cooking,
 173 heating and construction; environmental services such as air and water purification, watershed
 174 protection to control of run-off, soil stabilization, nutrient cycling, carbon sequestration (storage) etc;
 175 recreational facilities such as game reserves, zoos etc; medicinal plants for the treatment of various
 176 types of ailment; and food in the form of non-timber forest products. However, awareness of these

177 forests benefits which contribute to a great extent to the development of socio-economic wellbeing as
 178 well as maintain good health conditions of human beings resulted into intense and unsustainable
 179 exploitation of forest resources for improved standard of living of human beings. This intense
 180 exploitation of forest resources led to forest degradation, which was mainly in the form of
 181 deforestation [24].

182
 183 [21] reported that forests had value in the locality and the highest benefit derived from forest
 184 resources was sources of fuel wood. [25] was of the opinion that it was more probable for local
 185 communities to consent to preservation and management of resources if they can derive some
 186 benefits from it.

187
 188 **Table 2. Distribution of farmers according to the benefits derived from or uses of the**
 189 **forest/forest products (n = 150)**
 190

Variables	Frequency	Percentages
Benefits derived from or uses of the forest*		
Maintains and restores soil fertility and stability	98	65.33
Helps protect water supplies	80	53.33
Provides the raw materials for crop support (e.g. yam stakes)	89	59.33
Provides the raw materials for agricultural implements (e.g. hoe)	86	57.33
Provides the raw materials for harvest and transport equipment (e.g. basket)	90	60.00
Provide raw materials for crop processing equipment (cocoa drying racks)	80	53.33
Provides raw materials for crop storage containers (e.g yam storage stakes)	86	57.33
Provides the raw materials for crop marketing equipment (e.g. basket and sacks)	85	56.67
Provides the raw materials for protecting crops (e.g. fencing and plant-based insecticides)	87	58.00
Provides the raw materials for food stores (e.g. wood ash placed in storage bins)	85	56.67
Provides the raw materials for packing and processing food	90	60.00
Provides the raw materials for boats, nets, traps, poles, poisons and fuel woods for fish preservation	87	58.00

192

193 3.3 Famers' participation in forest conservation

194 Considering its numerous benefits, forest must be conserved for future generations. Result in Table
 195 3 showed that only 26.67% of the respondents practiced selective exploitation of the forest
 196 resources, 26.00% took part both in afforestation and forest fire prevention and control, 13.33%
 197 each, participated in agro forestry and considered other alternative uses of forest, 10.60%
 198 participated in reforestation and 7.33% used alternative sources of energy besides fuel wood. This
 199 implies that participation in forest conservation among the farmers was very low. [26] is of the view
 200 that the level of community participation in the conservation of forest resources has been
 201 acknowledged as an indispensable component of sustainable development in general. Furthermore,
 202 community participation can help increase a common visualization of the way natural resources are
 203 supposed to be managed, build self-assurance and competence for cooperative action, recognize,
 204 develop and integrate local ideas, ways of life and principles.

205

206 **Table 3. Distribution of farmers according to participation in forest conservation (n = 150)**

207

209

210 3.4 Farmers perceived effects of community participation in utilization and conservation of 211 forest resources

212 Table 4 shows that the respondents had a positive perception on the fact that community
213 participation in forest conservation increases job opportunities among the participants with a mean
214 score of 4.65. It was followed by the perception that community participation in forest conservation
215 reduces poverty among participants (4.16). The farmers also perceived that community participation
216 in forest conservation increases food security (4.03). They also perceived that community
217 participation in forest conservation ensured sustainable growth and development of the forest (3.85).
218 The perception that community participation in forest conservation improves the level of living of the
219 farmers had a mean score of 3.72. This implies that community participation in the utilization and
220 conservation of forest resources was strongly and positively perceived by the farmers to increase job
221 opportunities, reduce poverty and increase food security. It was also perceived by the farmers that
222 utilization and conservation of forest resources ensure sustainable growth and development of the
223 forest and improve the level of living of the farmers.
224

225 **Table 4. Farmers' perceived effects of community participation in utilization and**

229

230 3.5 Relationship between farmers' socioeconomic characteristics and perceived effects of 231 community participation in utilization and conservation of forest resources

232 This study estimated the relationship between the farmers' socioeconomic characteristics perceived
233 effects of community participation in utilization and conservation of forest resources. Table 5 presents
234 the linear regression estimates for the relationship. With reference to the overall fit of the regression
235 model, the obtained R^2 (0.7745) and R^2 adjusted (0.7601) suggests that the weighted combination of
236 the predictor variables was jointly significant in explaining each of the dependent variables.
237

238 The result reveals that age had a negative (-0.009142: $p < 0.01$) and significant relationship with
239 farmers' perceived effect of community participation in utilization and conservation of forest resources.
240 Household size was found to have a positive and significant (0.0169081: $p < 0.05$) relationship with
241 farmers' perceived effect of community participation in utilization and conservation of forest resources.
242 Similarly, education (0.0503444: $p < 0.1$) and farm size (0.1228889: $p < 0.1$) also had a positive and
243 significant relationship with farmers' perceived effects of community participation in utilization and
244 conservation of forest resources. With the existence of these relationships between the variable, the
245 null hypothesis is rejected. It implies that the farmers' perceived effects of community participation in
246 utilization and conservation of forest resources were controlled by their age, household size,
247 education and farm size. As the farmers grow older, their perception on the effects of community
248 participation in utilization and conservation of forest resources becomes weaker or more negative.

249 However, the farmers' perceived effects of community participation in utilization and conservation of
 250 forest resources becomes stronger or more positive with increase in the farmers level of education
 251 and farm size.

256 4. Conclusion

257 Farmers in the study area were within their active and productive ages with good farming
 258 experiences. They produced crops and livestock under small holdings which led to involvement in
 259 other non-farm occupations for additional income and improvement in their standard of living. The
 260 forest was an important part of the farmers' lives since they benefitted in several ways from its
 261 products. However, the farmers' participation in conservation of the forest was very low despite
 262 having a positive perception on the fact that community participation in forest conservation could
 263 increase job opportunities; reduce poverty, increase food security among others. Such perceptions
 264 were determined by the farmers' age, household size, education and farm size.

265 5. Recommendations

266 Based on the findings of this study the following recommendations were made;

- 267 i. There is need for sensitization of the farmers on the importance of participation in forest
 268 conservation by all stakeholders in forest conservation (Both government and non-
 269 governmental organizations).
- 270 ii. The farmers should be encouraged by forest conservation agencies to form associations for
 271 improved participation in forest conservation.
- 272 iii. Governments at all levels should enact policies that will encourage and increase the farmer
 273 participation in conservation of the forest.

274 COMPETING INTERESTS

275 Authors have declared that no competing interests exist.
