

**Study of Functional outcome of three or four part proximal humerus fracture treated with primary hemiarthroplasty**

**Abstract**

**Introduction:** The treatment of displaced proximal humerus fracture is challenging and at the same time controversial. It varies from conservative to surgical management. Primary hemiarthroplasty in proximal humerus fracture is indicated in three or four part fracture or fracture dislocations. Main aims of treatment in open reduction and internal fixation are preservation of vascularity of humeral head and an anatomical reduction of fracture, which is difficult in three or four part fractures of proximal humerus. Hence we studied functional outcome of 3 or 4 part proximal humerus fracture treated with primary hemiarthroplasty.

**Materials and Methods:** Fifteen patients diagnosed with three or four part proximal humerus fracture underwent primary hemiarthroplasty between January 2017 and June 2018. Functional evaluation based on constant score and radiological assessments by periodic X-rays were done. All patients were operated in a 'beach chair position'. The lesser and greater tuberosity were dissected with their tendinous attachments and were later reattached to the proximal humerus for stability of the prosthesis.

**Results:** Mean follow up was 14.3 months (range 11-18 months). Mean age was 61.20 years (range 48-78 years). Ten patients were male and five were female. Mean Constant score was 55.25 (range 43.2-64.4) points at final follow up. . Mean anterior elevation was 119.5°(range 75<sup>0</sup>-150<sup>0</sup>). Mean active abduction was 104° (range 57° - 130°). Mean external rotation was 24° (range 16° - 30°). Proximal migration of tuberosity was present in two patients. Two patients had moderate pain at their final follow up. Twelve (i.e., 80%) patients were satisfied about their functional outcome.

31 **Conclusion:**The study showed hemiarthroplasty is a better option in treating  
32 proximal humerus fracture in elderly but also is a viable alternative to  
33 osteosynthesis for grossly comminuted proximal humerus fractures in young  
34 adults.

35 **Key Words:**Proximal humerus fracture,primary hemiarthroplasty,tuberosity  
36 healing, Neer's Prosthesis.

37

### 38 ***Introduction***

39 Proximal humerus fracture comprises 4–5% of all fractures.<sup>(1)</sup> Typically occurs in a  
40 bimodal distribution in older women as a result of low-energy falls or in younger  
41 men as a result of high-energy trauma.<sup>(2,3)</sup> The treatment of displaced proximal  
42 humerus fracture is controversial. It varies from conservative to surgical  
43 management. With continued advancement in techniques and implants surgical  
44 fixation of proximal humerus is gaining popularity. Surgical management includes  
45 close reduction and percutaneous pinning, open reduction, and internal fixation  
46 with locking compression proximal humerus plate and hemiarthroplasty.<sup>(4)</sup>  
47 However, complication rates are still high in humeral head preserving procedures.  
48 In particular, osteonecrosis of humeral head remains unchanged even with the  
49 most modern of techniques.Thus main aim of treatment with Open reduction and  
50 internal fixation (ORIF) are preservation of vascularity of humeral head, an  
51 anatomical reduction of fracture, and good functional outcome of the shoulder  
52 which is difficult to achieve in three and four part fractures of proximal  
53 humerus.Hence nowadays Primarily shoulder hemiarthroplasty is indicated in  
54 patients with grossly displaced three and four part fractures or fracture  
55 dislocations, split head fractures, impacted fractures with loss of over 40%  
56 articular surface, and anatomical neck fractures of proximal humerus where more  
57 chances of osteonecrosis are present.<sup>(5-8)</sup>Neer had described good and  
58 satisfactory results after primary shoulder hemiarthroplasty in displaced three  
59 and four part fractures.<sup>(9)</sup>Initially first generation monoblock prostheses were  
60 used by Neer in 1970<sup>(9)</sup> then replaced by second generation modular prostheses

61 which provided better soft tissue balancing and good range of motion. Third  
62 generation prostheses were introduced in 1991 recreating anatomy of proximal  
63 humerus more accurately and hence more adaptable to the individual bony  
64 anatomy.<sup>(10,11)</sup> Post operatively Success of shoulder hemiarthroplasty depends on  
65 soft tissue integrity with reattachment of the tuberosities, bone quality, glenoid  
66 bone stock, stem height, version of the prosthesis, and soft tissue balancing.  
67 Hence researchers want to study the functional outcome of three or four part  
68 proximal humerus fracture treated with primary hemiarthroplasty and to compare  
69 the results with other similar published studies.

70

## 71 ***Materials and Methods***

72 15 patients diagnosed with three or four part proximal humerus fracture (graded  
73 according to Neer's classification) based on antero-posterior and oblique  
74 radiographs of the shoulder (Fig. 1) underwent primary hemiarthroplasty  
75 between January 2017 and June 2018 at KIMS(Krishna Institute of Medical  
76 Sciences)hospital were included in this study. If there was difficulty in obtaining  
77 the axillary view due to a patient's pain or apprehension, a modified axillary view  
78 such as a Velpeau view can be obtained, allowing the patient to remain  
79 comfortable in a sling. Neer classification system of Proximal Humerus Fracture is  
80 based on the anatomical relationship of four segments: humeral shaft, Greater  
81 tuberosity, lesser tuberosity and head with articular surface. Each segment is  
82 considered as separate part in the fracture if there is more than 1cm of  
83 displacement or 45° of angulation .<sup>(12)</sup> Although the Neer classification has  
84 demonstrated poor inter and intra-observer reliability, it is still commonly used,  
85 due to its simplicity.<sup>(13)</sup> All patients had acute injuries and were operated within 10  
86 days of injury. Computed tomography (CT) scan with 3-D reconstruction (Fig. 2)  
87 was done in all patients who helped in planning the surgical management. For  
88 preoperative planning of arthroplasty, an AP view of the contralateral humerus is  
89 used to template the planned length and height of the implant. Patients were  
90 discharged on post-operative day 5 and followed up on outdoor basis and were  
91 assessed according to a predetermined Score. Clinical and functional assessments

92 were done by Constant score.<sup>(14)</sup> Constant score consists of 0–100 points for single  
93 shoulder. It is divided into subjective and objective components. Subjective  
94 component consists of pain (15 points) and activities of daily living (sleep, work,  
95 and recreation/sports activities) (20 points). Objective component consists of a  
96 range of motion (40 points) and power of muscles (25 points) around shoulder.  
97 Patients were followed postoperatively at 2 week (at the time of suture removal),  
98 6 week then monthly for next 3 months, and then 3 monthly till the last follow-up  
99 till radiological bony union of the tuberosities was seen. All the patients were  
100 atleast followed up for 1 year. Radiological assessment was done with X-rays of  
101 shoulder in antero-posterior and axial views, if possible and X-rays were  
102 evaluated to assess tuberosity position and its bony union with the proximal  
103 humerus, any resorption of tuberosity, distance of top of the humeral head from  
104 acromion, and development of radiolucency at bone cement interface.  
105 Postoperative infection and loosening of implant were also recorded. For  
106 postoperative infection, assessment of wound healing, implant exposed, discharge  
107 from operative site and blood parameters like complete blood count was done. For  
108 loosening of implants, serial radiographs were assessed to see any signs of  
109 radiolucency at bone cement interphase.

## 122 **Operative procedure**

123 All patients were operated in beach chair position with the head of the bed  
124 elevated approximately 45°.The freely draped arm can be  
125 extended/hyperextended at the patient's side which help proximal humerus for  
126 canal reaming, cementation, and implantation of prosthesis. The standard  
127 Deltopectoral approach was used (Fig. 05). Significant adhesions and hematoma  
128 were encountered which were removed from the subdeltoid space. The fracture  
129 line between the tuberosities is almost always located just posterior to the  
130 groove. The first part of the procedure is getting control of the tuberosity  
131 fragments. In cases of arthroplasty for three-part fractures, 1<sup>st</sup> osteotomize the  
132 lesser tuberosity from the humeral head, in essence creating a four-part fracture  
133 (Agarwal et al., 2016). The humeral head is removed, after which the tuberosities  
134 are tagged with heavy sutures (Fig. 06). Three sutures are placed at the  
135 bone-tendon interface of the greater tuberosity, and one or two are placed in the  
136 lesser tuberosity fragment. Next, the humeral canal is exposed and prepared with  
137 sequential reaming. Preoperative films and implant measurements can also be  
138 used to assess component to ensure proper height of implant.Trial prosthesis is  
139 used to check for correct size and placement of the prosthesis. If the trial  
140 prosthesis is loose, bone cement is used to fix stem into the humoral medullary  
141 cavity. All prostheses were inserted in 20–30° of retroversion by external rotating

142 and adducting the arm. The height of the prosthetic stem was determined by the  
143 metaphyseal calcar. In case of severe comminution, pectoralis major insertion  
144 was taken as a reference point. Anatomically, prosthetic humeral head lies  
145 approximately 5.6 cm proximal to the superior border of the pectoralis major  
146 tendon.<sup>(15)</sup> Fixations of the tuberosities around the prosthesis were done by  
147 making drill holes and were tied to the prosthesis and proximal humerus using  
148 Ethibond No. 5 sutures. Ethibond sutures were passed through the holes over fin  
149 and neck of the prosthesis to tightly secure the tuberosities with their soft tissue  
150 attachments (Fig. 07, 08). Postoperatively, shoulder immobilizer with sling was  
151 given to all the patients.

172 **Post-operative protocol**

173 Immediately after procedure patient is given shoulder pouch with immobilizer  
174 which is to be worn for the 1<sup>st</sup> 2 weeks continuous day and nights and  
175 simultaneously patient is started on a rehabilitation program containing active  
176 range of motion of the elbow, wrist and hand and passive range of motion of  
177 shoulder. External rotation is limited based on intraoperative assessment of  
178 repair of tuberosities. Internal rotation is allowed till chest/abdomen and no  
179 active external rotation or extension is allowed for the 1<sup>st</sup> 4 weeks. At the end of 2  
180 weeks post suture removal patient can remove the immobilizer while sleeping at  
181 nights. Post-operatively, at 4 weeks immobilizer is removed and passive range of  
182 motion and assisted active range of motion are encouraged. By end of 6 weeks  
183 light resisted External rotation, forward flexion, abduction and active internal  
184 rotation started along with pendulum exercises. Furthermore, radiographs should  
185 be taken at 6 weeks to assess tuberosity healing. When evidence of healing is  
186 found at approximately 6 to 8 weeks then active assistive with a pulley and  
187 isometric strengthening exercises for rotator cuff and deltoid are initiated. These  
188 strengthening exercises are continued for next 6 weeks. Daily activities such as  
189 personal hygiene and eating are allowed which helps to build early muscle  
190 strength and endurance. Patient is encouraged to perform exercises on a daily  
191 basis for at least 6 months preferably a year. Weight lifting activities are gradually  
192 allowed after 6 months.

## 193 **Results**

194 All patients were operated at Krishna institute of Medical Sciences, Karad. Mean  
195 follow up was 14.3 months (range 11-18 months). Mean age was 61.20 years  
196 (range 48–78 years). TEN patients were male and FIVE were female. Mean  
197 Constant score was 55.25 (range 43.2-64.4) points at final follow up. Anterior  
198 elevation of more than 150° was present in 1 patient and from 90° to 150° in 12  
199 patients. Less than 90° of anterior elevation was present in 2 patients. Mean  
200 anterior elevation was 119.5°(range 75<sup>0</sup>-150<sup>0</sup>). Functional range of abduction for  
201 shoulder was 60–120°. Thirteen patients in our study had a functional range of  
202 abduction. One patient had <60° and one patient had 130° of active abduction.  
203 Mean active abduction was 104° (range 57° - 130°). Mean external rotation was

204 24° (range 16° - 30°). Internal rotation was not satisfactory in two patients  
205 according to Constant scoring system. Proximal migration of tuberosity was  
206 present in two patients. These patients had decreased abduction. No pain to mild  
207 pain was present in 13 patients. Two patients had moderate pain at their final  
208 follow-up. Twelve (i.e., 80%) patients were satisfied about their functional  
209 outcome. Tuberosity migration in two patients and higher placement of  
210 prosthetic stem in one patient were the causes of discomfort in three patients.  
211 Clinically, this patient had mild pain on elevation above horizontal level. There  
212 were no intraoperative complications. No cases of neurological injury, infection,  
213 and instability were noted. Heterotrophic calcification was not found in any case.  
214 The revision was not done in any case.

215  
216 Fig. 13: Range of Movements at 1year follow up.

## 217 Discussion

218 The purpose of the study was to evaluate functional outcome after primary  
219 hemiarthroplasty in proximal humerus fracture. Primary hemiarthroplasty in  
220 displaced three and four part proximal humerus fracture was initially proposed by  
221 Neer<sup>(9)</sup> and found to have good results as compared to conservative management  
222 in all age group and better than osteosynthesis in elderly. In younger patients,  
223 with complex, grossly comminuted, or displaced fractures, primary

224 hemiarthroplasty can be considered as a primary treatment. Initial varus  
225 alignment  $>20^\circ$  is also consider a viable indication of primary hemiarthroplasty  
226 because of high failure rate in osteosynthesis.<sup>(16)</sup> Results of primary  
227 hemiarthroplasty are better than secondary hemiarthroplasty in cases of  
228 posttraumatic malunion, nonunion, and avascular necrosis of proximal  
229 humerus.<sup>(17-19)</sup> Researchers used Constant score for functional evaluation which is  
230 universally accepted and validated.<sup>(11)</sup> The major aims of hemiarthroplasty in  
231 fracture of proximal humerus are pain relief, early and adequate shoulder  
232 function, patient satisfaction, and strength. Advanced surgical techniques and  
233 anatomical tuberosity fixation correlate directly with the outcome. Factors that  
234 affect the tuberosity union are positioning of prosthesis, stable fixation of  
235 tuberosity, and bone quality (rate of non-union are higher in elderly and in  
236 osteoporotic bone).<sup>(16)</sup> Higher placement of prosthesis is associated with higher  
237 risk of tuberosity nonunion and pain.<sup>(16)</sup> Hence, the assessment of stem height  
238 at the time of implantation is important. During surgery, in neutral position, there  
239 should be a gap of at least 1 cm or one finger width between the implant and the  
240 acromion.

241 Boileau et al.<sup>(20)</sup> showed that tuberosity healing was a major determinant of  
242 functional outcome. In their study, 23% patients had detachment and migration  
243 of tuberosity, while in our study that was only 13.34%. Modern prosthesis has  
244 holes over proximal end of the prosthesis for better attachment and integration  
245 of tuberosities. Anatomical healing of tuberosity gives good functional outcome  
246 due to the restoration of rotator cuff anatomy. Tuberosity migration was the main  
247 complication in our study and produced inferior results in two patients (13.34%).

248 Castricini et al.<sup>(21)</sup> performed primary shoulder hemiarthroplasty in 57 patients.  
249 Mean Constant score was 59.2 at mean followup of 52 months in their study  
250 which reflects good function. In our study, mean Constant score was 55.25 after  
251 mean followup of 14.3 months. Although Constant score remains low in primary  
252 hemiarthroplasty, it is acceptable in low demanding elderly patients. Major  
253 advantage of hemiarthroplasty is pain relief which is the main factor for patient  
254 satisfaction. Castricini et al. mentioned very satisfactory results in 91% patient in  
255 spite of low Constant score.

256 Kontakis et al.<sup>(22)</sup> had done a large systemic review of literature with primary  
257 shoulder hemiarthroplasty for proximal humerus fracture. They reviewed 16  
258 similar studies with 810 shoulder hemiarthroplasty done for three or four part  
259 proximal humerus fracture and fracture dislocations. The mean active anterior  
260 elevation was 105.7° (10–180°) and mean abduction was 92.4° (15–170°). In their  
261 study, the main complication was associated with tuberosity healing which  
262 occurred in 11.15% cases. Heterotrophic ossification was found in 8.8% cases, and  
263 proximal migration of humerus head was in 6.8% cases. The mean Constant score  
264 was 56.63 (11–98).

265 In present study, no patient had severe pain. Two patients had moderate pain at  
266 their final followup, while 13 patients had zero to mild pain. Severe pain in  
267 hemiarthroplasty was related to the stiffness of shoulder. Early passive movement  
268 of shoulder was started in all patients, so stiffness did not develop in any patient.  
269 Our study showed that older age and comminution of fracture had significantly  
270 affected tuberosity healing.

271 Liu et al.<sup>(23)</sup> looked at 33 patients undergoing hemiarthroplasty for fracture and  
272 found that healing of the tuberosities was poor in 18 patients; those patients with  
273 abnormal tuberosity healing had significantly higher pain scores and lower  
274 functional outcomes .

275 The pain free adequate range of motion of shoulder is the primary goal in  
276 shoulder hemiarthroplasty. Tuberosity healing plays the main role in good range  
277 of motion and is an important determinant of functional outcome. This study had  
278 no control group, shorter mean followup of 14.3 months and small sample size (n  
279 = 15) were limitations of this study. Further study with large sample size and  
280 longer followups are required to access the factors related to wear rate and  
281 implant loosening.

## 282 **Conclusion**

283 The study showed that hemiarthroplasty in a grossly comminuted proximal  
284 humerus fracture is a viable alternative to osteosynthesis in middle age group and  
285 definitive mangment in elderly. Tuberosity healing plays main role in good range

286 of motion and better functional outcome after shoulder hemiarthroplasty.

287

### 288 **Consent and Ethical Approval:**

289 As per university standard guideline, participant consent and ethical approval  
290 have been collected and preserved by the authors.
