

MOUND DISTRIBUTION AND SOIL TRANSFORMATION BY *MACROTERMES BELlicosus* IN BAGUDO AND AUGIE IN KEBBI STATE, NIGERIA.

ABSTRACT

The study was carried out to determine the distribution and soil transformation by *Macrotermes bellicosus* species. Two local government areas of Kebbi State namely; Bagudo and Augie were selected for the study. Field survey and proximate analysis was used for the study, data generated were analysed using descriptive (Means) and inferential (ANOVA) statistics. Mounds were manually counted; where distance, height and basal circumferences were measured using measuring tape. Results obtained showed mound size was significantly different ($P < 0.05$) among the study area. Physical characteristics of mounds such as distance, basal circumference, height: were also significantly different ($P < 0.05$) in all the locations. Dry land and wet land showed no significant ($P > 0.05$) difference exhibited in physical characteristics. Results indicated significant ($P < 0.05$) difference in Cation exchange capacity (C.E.C), sand, silt, and clay, and all mineral elements in study locations. Mound soils differed: ($P < 0.05$) significantly in Cation exchange capacity (C.E.C), sand, silt, and clay and all the elements in study locations: In conclusion, termites: can be considered to be cheap agents of soil amendments which can help farmers in improving soil fertility.

Key words: Mounds, *Macrotermes bellicosus*, Physical characteristics, minerals, Abundance, distribution and soil transformation.

INTRODUCTION

Termites are social land dwelling insects, cosmopolitan and they are mainly found in tropical and sub-tropical areas [1]. Termites are usually small, measuring between 4 to 15 millimeters (0.16 to 0.59 inches) in length [2]. Through the activities of nesting and foraging, termites considerably modify the structure of the soil surface horizon; by enriching it with clay, increase its infiltration capacities and thus promote microbial metabolism and nutrient availability to woody plants. Similarly, improve in rain water infiltration, tunnels in soil allow rain water to soak in deeply and help to reduce runoff and subsequent soil erosion through bioturbation [3].

31 Thus, the nest building activities inevitably influence soil functions and processes and preserves
32 soil and ecosystem diversity [4]; [5]; [6]. They promote modification and redistribution of soil
33 materials [6]. [7], reported that due to the digging of termites and their decomposition of plant
34 material, mound soils are generally more fertile than other soil. [8], also said that mound soils
35 have been found to contain more water than the surrounding soils, a clear advantage for plant
36 growth in savannahs. [5], observed mound soils to contain higher content of phosphorus and
37 organic matter than the surrounding soils. The author also in his study collected soil samples from
38 top, middle and bottom of termite mounds and that of adjacent areas and observed a greater
39 content of potassium, phosphorus, calcium, magnesium, organic carbon and lower pH value in the
40 inner part of termite mounds in relation to adjacent soils of the area. [5], reported that, organic
41 matter decomposition and nutrient cycling are highly influenced by termites. Their mounds posed
42 problems to farming activities in the study area, thereby reduce land mass for crop cultivation.

43 Termites' mounds can be beneficial to agriculture, such as boosting crop yield and enriching the
44 soil. The presence of mounds in the field enables large amount of rain water to soak into the
45 ground and increase the amount of nitrogen in the soil, both essential for the growth of crops [9].
46 [5], reported that, termites modify the structure of the soil surface; they enrich the soil and also
47 promote microbial metabolism and nutrient availability to plants.

48

49 **MATERIALS AND METHODS**

50 A survey research was conducted in some selected local Governments areas of Kebbi
51 State, particularly at Bagudo and Augie. The areas were purposefully selected because of the
52 population and widespread of mounds across each landscape in the study area. Kebbi State is

53 located in north-western Nigeria and is bordered by Sokoto State, Zamfara State, Niger State.
54 Kebbi State lies between 10° 8' and 13° 15'N latitude; 3° 30' and 6° 2'E longitude [10]; [11]. The
55 elevation of the study area is between 250 and 350 meters above sea level. The soils in the areas
56 are categorized as reddish brown or brown soils of the semi-arid and arid regions. The soil pH
57 values range at 6.0 to 7.0 with a bulk density 1.4 g/cm³ [12].

58 The vegetation consists of Northern Savannah, that experience low rainfall of usually less
59 than 1000mm and the prolonged dry season (6-9 months) sustains fewer trees and shorter grasses
60 of about 1.5 - 2m and few stunted trees hardly above 15m. The vegetation has undergone severe
61 destruction in the process of clearing land for the cultivation of important economic crops such
62 as cotton, millet, sorghum, cowpea, and maize [13]. The areas have an average temperature of
63 18.3°C with a rainy season from May to October during which showers occur. From late October
64 to February as the cold season, the climate dominated by the Harmattan wind blowing Sahara
65 dust over the land [14].

66 A simple random sampling technique was used to select mounds between the months of
67 April, 2015 to June, 2016 in the study area. The selected local governments areas were; Bagudo
68 and Augie. In each Local Government area six (6) sample plots measuring 500/20 m/sq were
69 selected, (three plots both from dry and wet land). Termite mounds were surveyed by transect
70 walk by foot, in each of the sample plot and abundance was observed by counting their
71 numbers in each plot, while distance, height and basal circumference were determined by
72 measuring with a tape.

73 Soil samples were collected for chemical analyses; two plots each from both dry land and
74 wet lands. During soil sampling; soil samples from the mounds were collected. In collecting

75 samples, exposed parts of mounds were scraped off and 1.0 Kg of soil samples from each point
76 was collected separately. Collected soil samples were sun-dried, ground, sieved through 2.0 mm
77 sieve. They were then packaged into bags separately and labeled accordingly, taken to the Soil
78 Science Laboratory of the Faculty of Agriculture Usmanu Danfodiyo University Sokoto for the
79 analyses, a proximate analysis was used to determine the nutrients composition of soil samples
80 using standard methods [15].

81 The data generated from field survey and proximate analysis was analyzed using
82 descriptive (means) and inferential statistics (ANOVA).

83

84 **RESULTS**

85 From the results of mound distribution in the dry land Bagudo was observed to record
86 number of mounds than Augie as follows 49 and 23 in dry land respectively (Table 1). While in
87 wet land Bagudo recorded higher number of mounds (38) compared with Augie (21). The
88 circumference results reveal that Bagudo dry land recorded higher circumference of 599.95.
89 Bagudo was observed to have 355.81, as circumference in the wet land when compared with
90 Augie that have 263.37 as the circumference. These could be attributed to the fact that Bagudo
91 area lies closely to the guinea savannah while Augie was closely to Niger Republic and it is
92 semi-arid area

93 The physical characteristics of mounds within the locations and land types in the study area
94 are shown on table 2. The measured physical characteristics were distance, height and basal
95 circumference. There was no significant ($P>0.05$) difference in terms of distance in all land type
96 in the locations. Height and basal circumference of the mounds for all the land type in all

97 locations followed the same pattern with distance. For distance Bagudo and Augie recorded
98 similar results with average means as follows; 4.33 and 4.22 on dry land respectively. In wet
99 land the highest mean average of distance was recorded in Bagudo with mean average of 4.56
100 and Augie with mean averages of 3.78.

101 Mineral elements, calcium, magnesium, potassium, sodium, phosphorus, zinc, copper and
102 iron studied in both dry and wet land in table 3. Calcium was significantly ($P<0.05$) higher in
103 Bagudo compared to Augie with mean average as thus, 0.850 and 0.585 in dry land respectively.
104 Phosphorus recorded significantly ($P<0.05$) higher mean average in Augie than Bagudo at both
105 the condition (dry and wet land).

106 Soil pH, organic carbon, organic matter, Nitrogen, Cation Exchange Capacity, sand, silt,
107 and clay in the soil of the selected land type and locations are shown on table 4. Soil pH
108 significantly ($P<0.05$) differed in all the locations of the study. In dry land Bagudo was observed
109 to be significantly ($P<0.05$) differ in pH value than found in Augie which were as follows; 7.70
110 and 6.65 per cent respectively. While in wet land Bagudo was observed to have higher ($P<0.05$)
111 pH value, followed by Augie, Similarly in dry land organic matter was found to differ ($P<0.05$)
112 in all locations. While in wet land the highest ($P<0.05$) mean average of organic matter was
113 observed in Bagudo and the least ($P>0.05$) was found in Augie. Nitrogen percentage in dry land
114 was observed to be higher ($P<0.05$) in Bagudo compared to Augie, whereby in wet land the
115 maximum ($P<0.05$) content of nitrogen was observed in Bagudo and the minimum was found in
116 Augie.

117

166 **Discussions and conclusion**

167

168 *Macrotermes bellicosus* are found everywhere and have many mounds in the study area.
169 Their abundance may be due to the fact that they are tropical insects and vegetation and
170 climatic condition favours their activities. This was in agreement with [16], who reported that
171 termite species are abundant in the tropics. [17], also reported the abundance of mounds as due
172 to soil type and vegetation. The observation was in conformity with [18], who reported 3-10
173 mounds per hectare (ha^{-1}) for *Macrotermes bellicosus* species and termites' diversity is high in
174 Africa. Dry land was observed to have more mounds than wet land. This could be attributed to
175 the fact that dry land has less moisture content unlike wet land that contains high moisture
176 content which tends to or may hinder their activities and moisture also destroys their food,
177 while dry land promotes more foraging activities.

178 Physical characteristics of mounds, such as basal circumference, height and distance in
179 dry and wet lands varied in size and height in locations of the study which could be attributed
180 to the nature of the soil, land type and climatic conditions in the area. These findings were in
181 agreement with that of [19]; [20], whose reported that mounds have elaborate and distinctive
182 forms; termite builds tall, wedge-shaped mounds with long axis in different locations. Dry land
183 was observed to record higher pH value compared to wet land, while termite mounds and the
184 surrounding soils were observed to record varying pH value. Mound soils observed in different
185 locations during the study showed higher pH value. This may be due to termite waste and
186 saliva secretion which affect acidity and alkaline of mound soil. [21], reported that termite
187 mounds with higher pH value which could be related to accumulation of calcium carbonate.
188 Nitrogen percentage in study locations differed according to land type (dry land and wet land)

189 and also mound soils. This could be attributed to termite wastes accumulation in mound soils.
190 [22], reported no significant difference in the percentage of nitrogen in mounds soils.

191 It was also observed that the percentage of organic carbon (O.C) in all the locations of
192 the study differed (dry land, wet land) mound soils. In land type higher organic matter was
193 observed in the wet land than in the dry land and this could be attributed to the deposit of
194 materials by rain water unlike than in the dry land. Mound soils were observed to have more
195 organic matter than surrounding soils. This could be due to the fact that termites mixed sand
196 with faeces, saliva and residues of food which contributed in making mounds richer. This was
197 similar to [21]; [17], whose reported that when comparing mound soils with the surrounding
198 soils, the difference between them may not vary wide. Sand, clay and silt particles as well as
199 Cation Exchange Capacity were found to differ according to the locations and land type. This
200 was in agreement with [23]; [21], reported that termite mounds have finer particles. Calcium
201 (Ca), Magnesium (Mg) Potassium (K) and Sodium (Na), in all the locations and land type
202 differed significantly. Dry land contained more calcium compared to wet land, while Mg, K
203 and Na were higher in wet land than dry land. This may be due to less moisture of the dry land
204 compared to wet land. This was similar to [22], who reported that termite activities
205 significantly increased cation, micro-nutrients, and organic matter content. There was no
206 difference in Phosphorus (P), Zinc (Zn), Copper (Cu) and Iron (Fe) both in dry land and wet
207 land in mound soils. This was in conformity with [17]; [21], who reported that the result of
208 phosphorus and mineral elements in mound soil was higher. [22], reported that termite
209 activities significantly increased exchangeable bases, cations, micro- nutrients, organic matter
210 content and also pH value.

211 **Conclusion:**

212 The study concludes that termites are abundantly distributed in the location of the study
213 and their mounds have good compositions of nutrient elements, which may promote
214 agricultural activities such as soil aeration and water filtrations. They can be considered to be
215 cheap agents of soil amendments which can help farmers in improving soil fertility.

216 **AUTHORS' CONTRIBUTION**

217 The research work was carried out in colorations with all Authors. Authors S H A
218 designed the study, managed the literature searchers and wrote the protocol and the first draft of
219 the manuscript. Authors HMB, MMY and AA finished the design, protocol and check the draft
220 report. All Authors read and approved the final manuscripts.
