1

EFFICACY OF DIFFERENT ORGANIC MANURES ON GROWTH AND YIELD PERFORMANCE OF ORGANICALLY GROWN TOMATO

ABSTRACT

The field experiment was conducted in the Horticultural farm of Sher-e-Bangla Agricultural University, Sher-e-Bangla Nagar, Dhaka -1207 during the period from October 2014 to March 2015 to find out the efficacy of different organic manures and different varieties on the growth, yield performance of organically grown tomato. The experiment comprised of two different factors such as Factor A. four types of organic manure such as M_0 = Control (No organic manures application), M_1 = Cowdung (30 t/ha), M_2 = Poultry manure (25 t/ha) and M_3 = Vermicompost (20 t/ha). Factor B. three types of variety such as V_1 = BARI tomato 15, V_2 = BARI tomato 14 and V_3 = BARI tomato 2. The experiment was laid out in Randomized Complete Block Design (RCBD) with three replications. Encouraging responses were monitored in all respects. Among the treatment combination M_2V_1 (Poultry manure + BARI Tomato 15) showed the highest plant height, maximum number of flower cluster, number of flower per cluster, number of fruits per cluster and number of fruit per plant with improved fruit size. The maximum yield (86.25 t/ha) was recorded from the treatment combination of M_2V_1 (Poultry manure + BARI Tomato 15), while the treatment combination of M_0V_3 (Control treatment + BARI Tomato 2) gave the minimum yield (31.25 t/ha). Therefore, BARI Tomato 15 coupled with poultry manure can be the most suitable for enhanced yield and can be considered a noble practice in sustainable agriculture.

17 **1. INTRODUCTION**

18

19 Over the last two decades, organically grown vegetables have generated significant interest among 20 the consumers and scientists due to healthier products and safer characteristics to human health. 21 Consumers demand for organic vegetables has also on the rise. Therefore, sustainability of vegetable 22 production with higher yield is the prime need to meet consumer demand. Furthermore, sustainable 23 vegetable production has been often reported as an environmentally-friendly production system able to produce food with minimal hazardous effect to ecosystems and environment as well as minimal use 24 25 of off-farm resources [1]. However, the major drawback of organic vegetable production is the lower 26 yield compared to conventional agriculture [2, 3]. Therefore, farmers prefer to use commercial 27 synthetic chemical fertilizers for vegetable production. However, extensive use of inorganic fertilizer 28 may lead to environmental pollution including contamination of groundwater, and soil acidification as well as increase de-nitrification resulting in higher the emission of nitrous oxide (N₂O) to the 29 30 atmosphere which is responsible for global warming. Therefore, there is prime need to bring new 31 management practice to increase nutrient availability, plant uptake and assimilation, reduce disease intensity in order to close the gap between organic and conventional yields [4, 5]. Application of 32 33 organic manures can be an effective practice to produce tomato in a sustainable production system. 34 Organic manure is a source of food for the innumerable number of microorganisms and creatures like earthworm who breaks down these to micronutrients, which are easily absorbed by the plants. 35 Organic manure plays a direct role in plant growth as a source of all necessary macro and 36 37 micronutrients in available forms during mineralization, improving the physical and physiological 38 properties of soils. Organic manures such as cow dung, poultry manure and vernicompost improves 39 the soil structure, aeration, slow release nutrient which support root development leading to higher

40 growth and yield of tomato plants. The macronutrients calcium and micronutrients boron, manganese, molybdenum and iron are important for tomato cultivation. Biologically active soils with adequate 41 42 organic matter usually supply enough of these nutrients [6]. Tomato (Lycopersicon esculentum L.) is 43 one of the most popular and versatile vegetables in the world which is cultivated in almost all parts of 44 Bangladesh under both field and greenhouse conditions. Tomato fruits are eaten raw or cooked and 45 other dishes like as soups, juice, Jam, Jelly, ketchup, pickles, sauces, conserves, puree, paste, 46 powder and other products. In terms of human health, tomato is a major component in the daily diet 47 and constitutes an important source of minerals, vitamins and antioxidants, like lycopene. Lycopene pigment is a vital anti-oxident that helps to fight against cancerous cell formation as well as other kind 48 49 of health complications and diseases [7]. Nevertheless, it plays a vital role in providing a substantial 50 quantity of vitamin C and A in human diet [8]. Increasing the production and improving the keeping 51 quality of tomato are of paramount importance, now-a-days, for meeting the internal demand of the 52 consumers'. Hence efforts should be given to identify varieties with high yield potential in organic 53 production system influenced by the application of different organic manures. Considering the above 54 perspective, the present study was undertaken to identify the suitable tomato variety and the efficacy 55 of different organic manures which can promote growth, increase yield of tomato in a sustainable and 56 environment friendly way.

60

59 2. MATERIAL AND METHODS

61 2.1 Experimental Site

The experiment was conducted at the Horticultural farm of Sher-e-Bangla Agricultural University, 62 63 Dhaka, Bangladesh from October 2015 to February 2016. The location of the experimental site was 23º74'N latitude and 90º35'E longitude and at an elevation of 8.2 m from sea level. The climate of 64 65 experimental site was under the subtropical climate, characterized by three distinct seasons, the 66 winter season from October to February and the pre-monsoon or hot season from March to April and 67 the monsoon period from May to October .The soil of the experimental area belongs to the Modhupur 68 Tract (AEZ No 28). It had shallow red brown terrace soil. The selected plot was medium high land and 69 the soil series was Tejgaon.

70

71 2.2 Planting Material

Three varieties of tomato were used in this experiment viz, V_1 = BARI tomato 15, V_2 = BARI tomato 14 and V_3 = BARI tomato 2.Tomato seeds were collected from Vegetable division, Horticulture Research Centre (HRC), Bangladesh Agricultural Research Institute (BARI), Gazipur, Bangladesh.

75 2.3 Organic Materials

Four types of organic manure coded as M_0 = Control (No organic manure), M_1 = Cow dung (30 t/ha), M₂ = Poultry manure (25 t/ha), M_3 = Vermicompost (20 t/ha)

78

79 **2.4 Experimental Design and Treatments**

The experiment was laid out in Randomized Complete Block Design with three replications. There were altogether 12 (4 x 3) treatments combination used in each block were as follows; M_0V_1 , M_1V_2 , M_2V_3 , M_0V_2 , M_1V_3 , M_3V_1 , M_0V_3 , M_2V_1 , M_3V_2 , M_1V_1 , M_2V_2 , M_3V_3 . The experimental plot was first divided into three blocks. Each block consisted of 12 plots. Thus, the total numbers of plot were 36. Different combinations of treatments were assigned to each plot as per design of the experiment. The size of a unit plot was 2.4m ×2.4m. A distance of 0.5 m between the plots and 1.0 m between the blocks were kept.

87

88 **2.5 Growth Condition of Tomato and application of Manures**

The experimental land area was prepared by several ploughing and cross ploughing with a power tiller followed by laddering to bring about a good tilth. The land was leveled, corners were shaped and the clods were broken into pieces. The weeds, crop residues and stables were removed from the field. Total organic manures were applied according to their treatment and finally leveled. Thirty daysold healthy seedlings were transplanted at the spacing of 60cm × 40cm in the experimental plots. Thus the 24 plants were accommodated in each unit plot.

95 2.6 Data Collection and Analysis

96 Five plants were randomly selected from each unit plot for the collection of data. The plants in the 97 outer rows and the extreme end of the middle rows were excluded from the random selection to avoid 98 the border effect. The height of the plants was measured from the ground level to the tip of the highest leaves. The data obtained for different parameters were statistically analyzed to find out the 99 100 significant difference of variety and different manure application on yield and yield contributing 101 characters of cabbage. The mean values of all the characters were calculated and analysis of 102 variance was performed by the 'F' (variance ratio) test. The significance of the difference among the treatment combinations means was estimated by the Duncan's Multiple Range Test (DMRT) at 5% 103 104 level of probability.

105

106 3. RESULTS AND DISCUSSION

107

108 3.1 Plant height (cm)

109 Application of organic manures exhibited a significant influence on the height of tomato plants at 30, 110 45, and 60 days after transplanting (DAT) and at final harvest (Figure 1). At 30 DAT, the tallest plant (35.68 cm) was found in the application of poultry manure (M_2) and the shortest plant (26.33 cm) was 111 recorded from control treatment (M_0). At 45 DAT, the plant height (59.32cm) was recorded from M_2 , 112 while the lowest (43.88cm) was recorded from M_0 . At 60 DAT, the longest plant (77.35cm) was recorded from M_2 and the shortest plant (62.08cm) was recorded from M_0 . At final harvest, plant 113 114 115 height ranged from 67.44cm to 83.90cm. The highest plant (83.90cm) was recorded from M₂, while 116 the lowest (67.44cm) was recorded from M₀. Poultry manure is rich in its nitrogen and nutrient 117 content. This favorable condition creates better nutrient absorption and favors for vegetative growth. 118 Consequently longest plant was found by application of poultry manure. This is an agreement with the 119 findings of [6].

120

121 Different varieties showed significant influence on plant height of tomato plants at different DAT and 122 final harvest (Figure 1). At 30 DAT, the tallest plant (33.71cm) was found from V₁ (BARI Tomato 15) 123 and the shortest plant (29.53cm) was found from variety V₃ (BARI Tomato 2). At 45 DAT, the highest plant height (53.77cm) was recorded from V₁, while the lowest (48.48cm) was recorded from V₃.The 124 125 plant height ranged from 70.31cm to 75.33cm at 60 DAT. The longest plant (75.33cm) was recorded from V₁ and the shortest plant (70.31cm) was recorded from V₃. At final harvest, the highest plant 126 127 (78.12cm) was recorded from V_1 , while the lowest (71.88cm) was recorded from V_3 . Organic matter 128 improves soil structure, increases the water holding capacity and promotes biological transformations 129 such as N-mineralization and enhances crop growth and development [9]. The results of this study 130 are also in agreement with the findings of [10, 11].

- 131
- 132

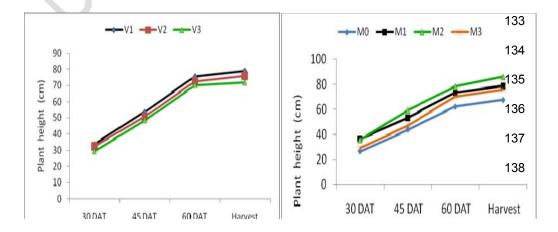

Figure 1: Effect of manures and variety on plant height of tomato (M₀ = Control, M₁ = Cowdung 140 (30 t/ha), M_2 = Poultry manure (25 t/ha) and M_3 = Vermicompost (20 t/ha), V_1 = BARI tomato 15, V_2 = 141 142 BARI tomato 14 and V_3 = BARI tomato 2

143 The variation was found due to combined effect of organic manure and variety on plant height at 144 different days after transplanting (Table 1). The maximum plant height (48.80cm) was recorded from 145 the treatment combination of M_2V_1 , while the treatment combination of M_0V_3 gave the minimum plant 146 height (16.66 cm) at 30 DAT. At 45 DAT significant differences in terms of plant height was observed 147 among the treatment combinations. However the largest plant (75.08cm) was recorded from the 148 treatment combination of M_2V_1 whereas the minimum (36.20 cm) was recorded from treatment combination of M₀V₃. At 60 DAT, the tallest plant (90.61 cm) was recorded from the treatment 149 combination of M₂V₁, while the minimum plant height (51.22 cm) was recorded from treatment 150 151 combination of M₀V₃. At harvest the maximum plant height (97.80 cm) was obtained from the 152 treatment combination M_2V_1 whereas the minimum (58.90 cm) was found from the treatment 153 combination of M_0V_3 .

	Plant height (cm)

156 In a column, means followed by same letter (s) do not differ significantly at 5% level of probability, M_0 157 = Control, M_1 = Cowdung (30 t/ha), M_2 = Poultry manure (25 t/ha) and M_3 = Vermicompost (20 t/ha),

 V_1 = BARI tomato 15, V_2 = BARI tomato 14 and V_3 = BARI tomato 2 158

159

160 3.2 Number of flower clusters per plant

161 162 Application of organic manures exhibited a significant influence on the number of flower cluster per 163 tomato plant (Table 2). The maximum number of flower clusters per plant (9.74) was recorded from 164 M_2 (Poultry manure), which was statistically identical (8.89) to M_1 while the minimum (8.27) was 165 obtained from M₀ (Control treatment).

166 A significant variation was recorded due to combined effect of different varieties on number of flower 167 clusters per plant under the present investigation (Table 2). The maximum number of flower cluster 168 per plant (10.61) was recorded from V₁ (BARI Tomato 15) and the minimum number of flower cluster 169 per plant (7.49) was obtained from V_3 .

170

139

The variation was found due to combined effect of organic manure and varieties for number of flower cluster per plant (Table 3). The maximum number of flower cluster per plant (11.64) was recorded from the treatment combination of M_2V_1 (Poultry manure + BARI Tomato 15) which was statistically identical to M_2V_2 (11.37) (Poultry manure + BARI Tomato 14), while the treatment combination of M_0V_3 (Control + BARI Tomato 2) gave the minimum (6.34) number of flower clusters per plant. This study is almost similar to the findings of [**12**].

178 **3.3 Number of flowers per cluster**

179 Organic manure varied significantly for number of flowers per cluster under the present study (Table 180 2). The maximum number of flower per cluster (9.24) was recorded from M_2 (Poultry manure), while 181 the minimum (8.41) was obtained from control (M_0). These findings are similar to the findings [9, 11].

Different varieties showed significant variation on number of flowers per cluster under the present trial (Table 2). The maximum number of flower per cluster (10.52) was recorded from V_1 (BARI Tomato 15) which was statistically similar to V_2 (BARI Tomato 14) and the minimum number of flowers per cluster (7.07) was found from V_3 (BARI Tomato 2).

186

177

The variation was also found due to combined effect of organic manures and varieties on number of flowers per cluster per tomato plant (Table 3). The maximum number of flower per cluster (11.43) was recorded from treatment combination of M_2V_1 (Poultry manure + BARI Tomato 15), while the treatment combination of M_0V_3 (Control + BARI Tomato 2) gave the minimum number of flowers per cluster (5.58).

193 3.4 Number of flowers per plant

194

195 Number of flowers per plant varied significantly due to application of different organic manures (Table 196 2). The maximum number of flowers per plant (58.25) was recorded from M_2 (Poultry manure), while 197 the minimum (36.11) was obtained from control treatment (M_0).

198 Different varieties showed significant variation on number of flowers per plant under the present 199 investigation (Table 2). The maximum number of flower per plant (48.05) was recorded from V₁ (BARI 200 Tomato 15) and the minimum number of flower per plant (44.47) was found from V₃ (BARI Tomato 2). 201 Application of manure facilitates slow release of nutrients and facilitates better nutrient uptake and 202 assimilation during reproductive growth which might be the reason for higher number of flower per 203 plant of tomato [11].

204

The variation was found due to combined effect of organic manures and varieties on number of flowers per plant (Table 3). The maximum number of flower per plant (91.16) was recorded from the treatment combination of M_2V_1 (Poultry manure + BARI Tomato 15), while the treatment combination of M_0V_3 (Control +BARI Tomato 2) performed the minimum number of flower per plant (26.40).

210 **3.5 Number of fruits per plant**

211 212 Number of fruits per plant differed significantly for application of different organic manures under the 213 present investigation (Table2). The maximum (42.07) number of fruits per plant was recorded from M_2 214 (Poultry manure), while the minimum (26.83) was recorded from M_0 (Control treatment). It was 215 revealed that number of fruits per plant increased in poultry manure. This might be caused that 216 Poultry manure contents high amount of nitrogen and nitrogen enhance photosynthesis, cell division 217 and cell enlargement. Similar trend of the results were found by [13] who reported that application of 218 manure improves microbial population and facilitates better nutrient uptake and increased the number 219 of fruits per plant.

220

221 Different varieties showed significant variation on number of fruits per plant under the present trial 222 (Table 2). The maximum (36.65) number of fruit per plant was recorded from V₁ (BARI Tomato 15) 223 and the minimum (31.63) number of fruits per plant was observed in V₃ (BARI Tomato 2). The reports 224 also supported to the results of [**5**, **9**, **11**].

226 Due to combined effect of organic manures and varieties showed significant differences on number of 227 fruits per plant (Table 3). The maximum (55.91) number of fruit per plant was recorded from treatment 228 combination of M_2V_1 (Poultry manure + BARI Tomato 15), while the treatment combination M_0V_3 229 (Control +BARI Tomato 2) gave the minimum (15.70) number of fruits per plant.

In a column, means followed by same letter (s) do not differ significantly at 5% level of probability, M_0 = Control, M_1 = Cowdung (30 t/ha), M_2 = Poultry manure (25 t/ha) and M_3 = Vermicompost (20 t/ha), V₁ = BARI tomato 15, V₂ = BARI tomato 14 and V₃ = BARI tomato 2

246 **3.6 Length of individual fruit (cm)**

247 248 Length of individual fruit varied significantly for different organic manures (Table 4). The maximum 249 length of individual fruit (7.97 cm) was recorded from M_2 (Poultry manure), while the minimum (6.29 250 cm) was recorded from M_0 (Control) which was statistically identical (7.71 cm) to M_3 (Vermicompost). 251 Similar types of results can be found by [**14**, **15**].

253 Different varieties showed significant variation on length of individual fruit under the present 254 investigation (Table 4). The maximum (7.66cm) length of individual fruit was recorded from V₁ (BARI 255 Tomato 15) and the minimum (6.66cm) length of individual fruit was obtained from V₃ (BARI Tomato 256 2). 257

The variation was found due to combined effect of organic manures and varieties for length of individual fruit under the present trial (Table 5). The maximum (10.94cm) length of individual fruit was recorded from treatment combination of M_2V_1 (Poultry manure + BARI tomato 15), while the treatment combination of M_0V_3 (Control treatment + BARI Tomato 2) performed the minimum (4.08 cm) length of individual fruit.

264 **3.7 Diameter of individual fruit (cm)**

265 266 Diameter of individual fruit significantly influence by different organic manures (Table 4). The 267 maximum (10.43 cm) diameter of individual fruit was recorded from M_2 (Poultry manure), which was 268 statistically identical with M_3 (9.44 cm) and M_1 (10.35), while the minimum (8.84 cm) was recorded 269 from M_0 (Control treatment). This trend is similar to [**16**, **17**].

271 Different varieties showed significant variation on diameter of individual fruit under the present 272 investigation (Table 4). The maximum (10.18cm) diameter of individual fruit was recorded from V₁ 273 (BARI Tomato 15) and the minimum (9.18cm) diameter of individual fruit was obtained from V₃ (BARI 274 Tomato 2).

275 276 Combined effect of organic manure and varieties varied significantly on diameter of individual fruit 277 (Table 5). The maximum (13.31 cm) diameter of individual fruit was recorded from treatment 278 combination of M_2V_1 (Poultry manure +BARI Tomato 15), while the treatment combination of M_0V_3 279 (Control treatment + BARI Tomato 2) gave the minimum (6.60 cm) diameter of individual fruit. Our 280 findings are in agreement with the findings of [**18**].

281282 3.8 Weight of individual fruit (g)

283 284 Weight of individual fruit varied significantly due to application of different organic manures (Table 4). 285 The maximum (123.33 g) weight of individual fruit was recorded from M_2 (Poultry manure), while the 286 minimum (91.69g) was recorded from M_0 (Control treatment). 287

A significant variation found different varieties on weight of individual fruit under the present trial (Table 4). The maximum (134.58 g) weight of individual fruit was recorded from V_1 (BARI Tomato 15) and the minimum (99.18 g) weight of individual fruit was recorded from V_3 (BARI Tomato 2).

291

270

The variation was found due to combined effect of organic manures and varieties on weight of individual fruit (Table 5) The maximum (176.66 g) weight of individual fruit was recorded from treatment combination of M_2V_1 (Poultry manure + BARI Tomato 15), while the treatment combination of M_0V_3 (Control treatment + BARI Tomato 2) performed the minimum (73.41 g) weight of individual fruit. Application of manures supply slow release of nutrients and increase the accumulation of carbohydrates which might be the reason for higher individual fruit weight. This was supported by [19, 20, 21].

300 3.9 Yield (kg/plant)

301

302 Yield per plant varied significantly due to application of different organic manures (Table 4). The 303 maximum (2.06 kg/plant) yield was recorded from M_2 (Poultry manure), while the minimum 304 (0.99kg/plant) was found from M_0 (Control treatment). Poultry manure is rich in its nitrogen and 305 nutrients content. These favorable conditions creates better nutrients absorption and favors the 306 growth and development of root system which in true reflects better vegetative growth, photosynthetic 307 activity. Consequently higher total yield would be obtained by poultry manure. The results also agreed 308 to the findings of [**22**].

309

Different varieties showed significant variation on yield per plant under the present investigation (Table 4). The maximum (1.75 kg/plant) yield was recorded from V_1 (BARI Tomato 15) and the

312 minimum (1.37kg/plant) yield was obtained from V₃ (BARI Tomato2). Similar trend of results were 313 found by [23].

314

315 The variation was found due to interaction effect of organic manures and varieties for yield per plant 316 (Table 5). The maximum (2.07 kg/plant) yield was recorded from treatment combination of M_2V_1 317 (Poultry manure + BARI Tomato 15), while the treatment combination M_0V_3 (Control treatment + BARI 318 Tomato 2) gave the minimum yield (0.75 kg/plant). Application of organic manure supply plant nutrients including micronutrients, improve soil physical properties like structure, water holding 319 capacity, increase the availability of nutrients and favors the beneficial microorganisms which 320 321 positively increase the yield and quality of tomato [24,25].

322

323 324

325

Table 4: Effect of organic manures and variety on fruit length, fruit diameter, individual fruit 326 weight and fruity yield per plant of tomato 327

Treatment	Length of individual fruit (cm)	Diameter of individual fruit (cm)	Individual Fruit Weight(g)	yield /Plant(Kg)
Mo	6.290 c	8.840 a	91.69b	0.993 c

333 In a column, means followed by same letter (s) do not differ significantly at 5% level of probability, M_0 334 = Control, M_1 = Cowdung (30 t/ha), M_2 = Poultry manure (25 t/ha) and M_3 = Vermicompost (20 t/ha), 335 V_1 = BARI tomato 15, V_2 = BARI tomato 14 and V_3 = BARI tomato 2

336 337

339

338 4. CONCLUSION

In this study, organic manures played a significant role in enhanced growth and yield performance of tomato in sustainable production system. BARI Tomato 15 coupled with poultry manure showed enhanced vegetative and reproductive growth with higher yield of tomato by slow and steady release of nutrients to the plants compared to other treatments. Thus the application of BARI Tomato 15 coupled with poultry manure can reduce the cultivation cost of tomato while minimizing pollution by excessive use synthetic fertilizers and could be considered as a good production strategy for obtaining high yields with lower impact on the environment.
