3	Analysis of post-harvest losses of yam in North-East Zone of Benue
4	State, Nigeria
5	
6	ABSTRACT
7	The study analyzed the post-harvest losses of yam in North-East Zone of Benue state,
8	Nigeria. It ascertained the level of postharvest losses of yam, identified the factors
9	precipitating postharvest losses of yam identified the strategies adopted by yam farmers
10	for reduction of postharvest losses of yam in North-East Zone of Benue State, Nigeria.
11	The study consisted of a total sample size of two hundred and four (204) yam farmers
12 13	drawn from three local govenrment areas of North-East Zone of Benue state. The result identified pest attack, storage method, temperature, disease and infection, poor
13 14	transportation, theft, underdeloped market and esposure of yam to sunlight as factors
14	precipitating post-harvest losses in the area. It also shows the result of the assessment of
16	yam farmers in the study area regarding the level of losses they experience at various
17	stages of yam postharvest activities. The value of the coefficient of multiple determinant
18	(R^2) , is 0808, which implies that about 80.8% of the postharvest losses of yam in the
19	study area is explained by the explanatory variables included in the model. The F-statistic
20	of the lead equation is significant at 1% (28.122). Coefficients of pest attack disease and
21	infections of yam, poor transportation facility, poor handling method used, excessive
22	exposure of yam to sunlight, werepositively related to postharvest losses of yam in the
23	study area at 1% level of significant. Coefficient of storage method, temperature of the
24	area and theft of yam in the study area were positive and significant to postharvest losses
25	of yam at 5% level of significant. Given that, the computed F- value (28.122), was
26	significantly higher than the tabulated F-value (9.33), at 1% level of significance, and
27	(3.11) at 5% level of significance; the null hypothesis was therefore rejected and the
28	alternative hypothesis was accepted. The study recommends provision of yam flour
29	processing factory, which will provide a ready yam market that will reduce postharvest
30	losses of yams and also increase the economic value of yams in the area.

31

32 Introduction

The phenomenon of postharvest losses of crop is an issue of great concern in the global community. This is essentially because, about one-third of the food produced in the world for human consumption every year, which is approximately 1.3 billion tones gets lost after harvest (FAO, 2018). By implication, 30% to 40% of all food crops produced in the world for human consumption is never consumed due to quantitative and qualitative
losses, which occur as food crop passes through postharvest chain or system.

Postharvest loss of food means the measurable quantitative and qualitative food losses in 39 the postharvest chain or system. The postharvest system comprises of interconnected 40 activities from the time of crop harvest through storage, processing, marketing and 41 preparation, to the final decision by the consumer to eat or discard the food (Kiaya, 42 2014). Qualitative food losses involve alteration in the physical condition or 43 characteristics of food produce which affect the nutrient/caloric composition and the 44 edibility of the food produce while quantitative food losses involve losses in terms of 45 volume or amount of food product. It is worthy of note that quantitative food loss in the 46 47 postharvest food chain is more common in developing countries, including Nigeria and Benue State (Kitinoja & Gorny, 1999). Quantitative and qualitative food losses do occur 48 49 at any stage in the postharvest chain. Also, economic losses can occur, as a subset of postharvest loss, in the event where the produce is subsequently restricted to a lower 50 51 market value due to either the qualitative or quantitative loss. When this occurs, the income of the producers and/or produce marketers is directly affected. This can 52 53 invariably affect their capacity to be effective in the next food production season and thereby, ensure continues availability of sufficient and quality food for their households. 54

55

Benue state is acclaimed the largest producer of yam in Nigeria and West Africa at large 56 (Phillips, Ogbonna, Etudaiye, Mignouna & Siwoku, 2013:15), with the largest vam 57 market (Zaki Biam yam market) in Benue North-East Zone and other numerous yam 58 markets across the state. The foregoing indicates a high level of yam production and yam 59 marketing activities in Benue and North-East Zone of Benue State in particular. This 60 prospect raises the general expectation that, the available yam markets should provide an 61 avenue whereby yam farming households can sale surplus yam produce so as to generate 62 enormous financial income, which will translate into a good standard of living and also 63 ensure the continuous availability of sufficient quality food for household consumption. 64

65

However, the findings of Verter and Becvarova (2014), Ivanda, Igbokwe and Olatunji
(2015) and Abu and Soom (2016), on the condition of farming households in Benue,

reveals that over 30% of yam farming households in Benue are still experiencing low 68 income from yam production and food insecurity. This findings suggests that, there might 69 70 be a prevailing significant level of postharvest losses of yam which may have been negatively affecting the standard of living and food security of yam farming 71 householdsinNorth-East Zone of Benue State. Again, several studies such as: Gernah, 72 Ukeyima, Ikya, Ode and Ogunbande (2013), Adamu, Mada and Kabri (2014), Sanginga 73 and IITA (2015), FAO (2018) and even studies that have been situated in the study area 74 like: Verter and Becvarova (2014), Ivanda, Igbokwe and Olatunji (2015) and Abu and 75 Soom (2016) have not established the factors precipitating postharvest losses of vams in 76 the study area, strategies adopted by yam farmers to reduce postharvest losses of yam, the 77 level of the losses of yam farming households in the study area. 78

79

80

81

82

Objectives of the study

- The foregoing underscores an existing knowledge gap that needs to be filled. Hence the study:
- 83 1. ascertained the level of postharvest losses of yam,
- 84 2. determined the factors precipitating postharvest losses of yam and
- 3. identified strategies adopted by yam farmers for reduction of postharvest losses of
 yam in North-East Zone of Benue State, Nigeria.
- 87

88

Hypothesis

Pest attack, poor storage, temperature, disease and infections, long distance from farm to
yam barn/market, poor transportation facility, theft, poor handling, sprouting, destruction
from crises, underdeveloped market and excessive exposure of yam to sunlight are not
factors precipitating postharvest loss of yam in North-East Zone of Benue State, Nigeria
Materials and Methods

The study area is Benue North-East Zone. This zone was established as a geo-political
demarcation alone side Benue North-West Zone and Benue South Zone. The Benue
North-East Zone, other words known as Zone A, is comprised of seven Local
Government Areas namely: Kwande, Logo, Vandeikya, Katsina-Ala, Konshisha, Ukum

and Ushongo. The population of Benue North-East Zone is estimated at 3,234,660,
whereas, an estimated figure of 285,454 has been recorded as regular households in the
Zone (National Population Commission, 2009). The State lies roughly within the lower
river Benue in the middle belt region of Nigeria, lying between Latitudes 6.5° and 8.5°
North and Longitudes 7.47° N and 10⁰ East.

- 110
- 111

The population of study consists of all yam farming households in North-East Zone of 112 Benue State, Nigeria made up of seven (7) Local Government Areas. The study 113 purposively selected three (3) local government areas (Ukum, Katsina-Ala and Logo) that 114 are most prominent in yam production in North-East Zone of Benue State. The three 115 Local Government Areas have a total of 1735 yam farming Households (Yam Farmers 116 Association, 2018). Four (4) council wards were randomly selected from each of the 117 selected local government areas, then seventeen (17) respondents were selected from 118 each of the council wards. This gave a total sample size of two hundred and four (204) 119 respondents. Primary data was obtained from fieldwork using questionnaire and focused 120 121 group discussion methods. Descriptive statistics were used to achieve the objectives of the study while multiple regression analysis were used to text the hypothesis of the study 122

152 **Result and Discussion**

153 Factors Precipitating Postharvest Losses of Yam in North-East Zone of Benue State

- 154 155
- Table 1: Factors precipitating postharvest losses of yam in North-East Zone of Benue State

Variables	Frequency	Percentage
Pest Attack	198	97
Storage method	202	99
Temperature	192	94
Disease and Infection	102	50
Distance	98	48
Poor Transportation	164	80
Theft	92	45
Handling of yams	182	89
Sprouting	68	33
Destruction from Crises	192	94
Underdeveloped Market	168	82
Exposure of Yam to Sunlight	201	99

156 157

157

The result on table 1 shows the opinion of yam farmers on factors that precipitate postharvest losses of yam in the study area. The result reveal that storage method used 99%(202) is the major cause of postharvest losses of yam in North-East Zone of Benue State. All the Focused Group Discussants in both Logo and Ukum Local Government Areas also submitted unanimously that poor storage is a major factor that precipitates postharvest loss of yam along other factors such as: poor handling method, destruction from crises, attack by pest, theft and fire disaster. The discussants noted accordingly that, the major storage method employed in the study area is the barn, which is basically a
traditional method of yam storage. Many of the discussants in both groups however, had
little knowledge about modern/improved methods of yam storage. This is consistent with
the findings of Osunde (2008), MFCL, et al (2004), Opara (2003) and FAO (1998) that,
yam barn is the principal traditional yam storage structure in the yam producing areas,
including Nigeria and Benue State.

The result on table 1 also reveals that, storage operations of yam farmers in the study area 172 may have been characterized by poor storage management in which case, they usually 173 fail to effectively monitor by regular inspection so as to prevent pest attack 97%(198) on 174 their stored yams and also reduce temperature 94%(192) in the barn so as to prevent yam 175 rot. This finding is in agreement with the findings of Opara (2003) on "yams postharvest 176 operation" by which he identified three main necessary conditions for successful yam 177 storage, which will involve minimal losses and they include: ventilation, reduction of 178 temperature and regular inspection of the stored yam. The following submission by a 179 discussant from Mbater council ward in Logo Local Government Area brings to light the 180 reason for yam losses during storage in the study area: 181

> For me, I usually get large yam harvest and I also store many yams, mostly in the barn, arranged in hips on the ground. So, regular checking on the yams becomes a problem and as a result, many times I notice pests like termites and rats attack my yams and even diseases also affects the yams.

Again, the result on table 1 indicates that exposure of yams to sunlight 99% (201) is another major cause of postharvest loss of yam in the study area as almost all of the sampled respondents concurred to this opinion. It is clear from this result that, such

182

183

184

185

186

exposure may have begun right at the time of harvesting where, following poor handling 191 89% (182), yams are left under the sun for a long time especially in situations where 192 there is shortage of work force during harvest. Understandably, therefore, when yams are 193 194 exposed to sunlight in this manner and days after on account of yam curing practice, there is always a tendency for yam rot and hence losses. This is because, the length of time for 195 proper curing cannot be precisely defined (FAO, 1998) and it depends on several factors 196 such as: condition of the yam at harvest, season and temperature of the environment. 197 When these factors at harvest and during vam curing are not effectively controlled, 198 exposure of yam to sunlight at harvest and during yam curing can easily become 199 excessive and thus yam rot and loss will be inevitable. 200

Furthermore, excessive exposure of yam to sunlight which precipitates yam losses in the study area occurs at the market setting. Given market activities of off-loading and loading of yams in the sun and the underdeveloped physical market structures in which yams are stored in the market for transaction, yam rot and losses becomes inevitable. This situation is captured in figure 4.1 below:

- 206
- 207
- 208
- 209
- 210
- 211

Figure 4.1: Loading of yams under the sunlight at Ukum yam market

Source: Field survey, 2018.

213

214

Interestingly, virtually all of the discussants in Logo Local Government Area 215 unanimously submitted that, the underdeveloped market structures provide ground for 216 market security persons to steal yams that are kept under their watch. That, one day of 217 security watch equals to one yam loss. The discussants averred that, this situation usually 218 compels yam farmers who sell their yams at the market to dispose their yams at subsided 219 220 rates, so as to avoid high economic loss. This establishes therefore, that yam losses are incurred from theft 45% (92) as a result of underdeveloped market structure 82% (168) in 221 the study area. 222

Table 1 also reveals that destruction from crises 94% (192) is another factor which precipitates postharvest loss of yam in the study area. This result has been confirmed by the submission of a discussant from Tswarev ward in Logo Local Government Area that:

226Out of ten wards in Logo Local Government Area, four227wards which include: Tombo, Mbagber,228Ukemberega/Tswarev and part of Iwuran have been

229 230

231 232 displaced, due to the herdsmen-farmer crises. Some of the residence and farms are occupied by Fulani. The herdsmen usually attack, destroy and burn yams in the barn and also expose some to their cattle to eat.

This finding corroborates the submission of Silas (2018) from his assessment of the 233 conflicts between Fulani-herdsmen and farmers in Kwara State of Nigeria that, food 234 crops which were cultivated on about 500 hectares of land with an estimated value of 235 N200 million was burned. This agrees with the position of FAO (2000) that, the impact 236 of conflict on agricultural practice, food security and standard of living of rural farmers 237 can be understandably placed in the context of the nature of contemporary conflicts 238 which are increasingly characterized by intra-country conflict, in which case, they are 239 usually fought in the countryside and/or rural areas rather than cities. Therefore, such 240 conflicts tend to have devastating effect on the rural population and agriculture which 241 goes to affect their standard of living including food availability and accessibility. 242 Nevertheless, all the discussants from the two groups were in agreement that many 243 farmers do move out their harvested produce at the rumor of potential attack, thereby, 244 minimizing the level of postharvest loss they incure during crises. 245

In the final analysis, therefore, it can be seen that factors such as: pest attack, storage method use and poor storage management, excessive exposure of yams to sunlight, destruction from crises, underdeveloped market, poor harvesting methods and temperature seem to be the factors precipitating postharvest losses of yam in North-East Zone of Benue State.

260

Table 2 shows the result of the assessment of yam farmers in the study area regarding the level of losses they experience at various stages of yam postharvest activities such as: harvesting, storage, transportation, sorting and marketing. The result revealed that greater losses are incured during marketing of yam. This is an indication that there are no readily

losses of yams in the study area.

²⁵⁸ 259

265 available markets and that farmers are not linked to buyers. This confirms the assertions of Nwafor et al (2019) that farmers are in need of market linkages. The high level of 266 267 losses during marketing could also be for the fact that farmers find difficult to carry their produce home at the close of the day, instead they chose to dispose it at any price or 268 better still abandon them in the market place in other not to spend another money 269 carrying them home. This calls for an organized marketing extension services in the area. 270 This result is cosistent with findings of Nwafor et al (2019) that reduction in the volume 271 of postharvest losses of root and tuber crop production is dependent on the agricultural 272 marketing extension services available to farmers in the study area. 273

Majority of the farmers experienced low level of losses during other activities except 275 marketing. This could be because of many years of experence and constant practice. The 276 farmers over the years have learnt to carry out yam production activities with minimal 277 losses. Handling of yams cuts across all other postharvest activities mentioned above. 278 There is no gain therefore, saving that, the manner by which yams are handled , 279 especially during harvesting, which is an activity that necessarily precedes other 280 postharvest activities can have serious implication for virtually all the postharvest 281 activities that follows. Improper handling of yams during harvest like leaving harvested 282 yams under the sunlight for a long period may predispose yams to easy bruising or injury 283 during yam transportation and sorting. 284

This finding confirms the findings of Ahmed and Rustagi (1987) from their study on marketing and price incentives in Africa and Asian countries that, food marketing by farming households in Nigeria mostly in the immediate postharvest period usually involves a lot of costs.

Source: Field Survey, 2018.

The strategies adopted by vam farmers for reduction of postharvest losses of vams in the 296 area icluded adoption of mordern storage facilities. 45.1% (92) of the yam farmers 297 sometimes adopt modern storage facilities. 22.5% (46) oftentimes adopt modern storage 298 facilitie, whereas, 21.6% (44) maintained that they always used it. Only 10.8% (22) of the 299 yam farmers submitted that they do not use modern storage facilities at all. The result 300 implies that the adoption or contineous use of mordern storage facilities is low in the area 301 as only 27% have adopted and hence use them consistently. This could be due to the 302 expensive and complex nature of the mordern storage facilities. 303

The result shows that 34.8% (71) of the yam farmers in the study area oftentimes try to 304 link-up with buyers or otherwise sell at farmgate prices to avoid spoilage. This is an 305 indication that farmers are in need of market linkages. Linking farmers to pottential 306 buyers or processors and consumers is a vital strategy of minimizing post-harvest losses 307 of yam. The regrettable consequence of adopting this measure is that, yam farming 308 309 households turn to incur economic loss as they do not always get the benefit of the full value of the yams they produce. This situation was captured in the opinon of a group 310 discussant from Tswarev in Logo Local Government Area that: 311

For me, I am happy that my yams stay in the ground till 312 maturity, but I cannot take the risk to store them because I 313 don't know the next thing that will happen, whether Fulani 314 will attack or something else and because of the many 315 money problems, I just sell the yams once I harvest them at 316 the farm. Although it is painful to me because I know that 317 these middlemen will end up benefiting more than me on 318 these yams, but do I have another choice? 319 The implication is that many of the farmers adopt sell at farm-gate as a measure to reduce 320

321 postharvest losses of yams, despite their awareness of the possible postharvest losses

involved in terms of economic losses, which may have adverse implication of adoptingsuch strategy for the standard of living of their households.

The result revealed that majority of yam farmers in the study area applies curing method, 324 fungicide, and pesticide as a strategy to reduce postharvest loss of yams. This may also 325 explain the low level of losses of yams in the study area. The use of pesticides controls 326 attack by pests like rodents, especially in storage facilities or structures such as the barn, 327 which has no anti-rodent guard fitted to it as it is with the case of elevated shade store. 328 Given that one of the main structural problem with the yam barn storage method is that, 329 disease causing fungi and pest can easily attack stored yams, it becomes reasonable and 330 safe to conclude that the prominent use of yam barn method for yam storage in North-331 East Zone of Benue State warrants the application of fungicide and pesticide as a measure 332 for the reduction of postharvest losses of yams. 333

Test of Hypothesis

The result of the ordinary least square multiple regression analysis used to test the hypothesis that, pest attack, storage method, temperature, disease and infections, long distance, poor transportation facility, theft, poor handling, sprouting, destruction from crises, underdeveloped market and excessive exposure of yam to sunlight are not factors precipitating postharvest losses of yam in North-East Zone of Benue State is presented in table 4 below.

Table 4: Factors precipitating postharvest losses of yam in North-East Zone of Benue State

345 Source: Field Survey, 2018.

NB: ***, ** and * represents 1%, 5% and 10% level of statistical significance respectively. Figure in brackets are t-values, whereas, the affirmative symbol + represents lead equation.

348

Based on the magnitude of the coefficient of multiple determination (R^2), the number of significant variables, the signs of the regression of the entire model as indicated by the Fstatistic, the Semi-log model was selected as the lead model. The value of the coefficient of multiple determinant (R^2) is 0808, which implies that about 80.8% of the postharvest losses of yam in the study area is explained by the explanatory variables included in the model. The F-statistic of the lead equation is significant at 1% (28.122), which implies that the model was well specified. Thus pest attack, storage method used, temperature of

³⁴⁶ 347

the study area, disease and infections, poor transportation facility, theft of yam, poor harvesting method and excessive exposure of yam to sunlight were observed to be the significant variables precipitating postharvest losses of yam in North-East Zone of Benue State.

Coefficients of pest attack (5.835), disease and infections of yam (3.096), poor transportation facility (2.300), poor handling method used (8.716), excessive exposure of yam to sunlight (5.317); were positively related to postharvest losses of yam in the study area at 1% level of significant. This implies an increase in these variables would lead to increase in postharvest losses of yam in the study area.

The coefficient of storage method used in the area (2.174), temperature of the area (2.444) and coefficient of theft of yam (2.206) in the study area were positive and significant to postharvest losses of yam at 5% level of significant. This implies a direct relationship of the variables with postharvest losses of yam in the study area. Therefore, increase in any of the variables would lead to increase in postharvest losses of yam in the study area.

Given that, the computed F- value (28.122), was significantly higher than the tabulated Fvalue (9.33), at 1% level of significance, and (3.11) at 5% level of significance; the null hypothesis was therefore rejected and the alternative hypothesis that; pest attack, storage method, temperature, disease and infections, poor transportation facility, theft, poor handling of yams, excessive exposure of yam to sunlight; are factors precipitating postharvest losses of yam in North-East Zone of Benue State was accepted.

377 Conclusion/Recommendation

The study thus concludes that, pest attack, storage method used, temperature, disease and 378 infections, poor transportation facility, theft of yams, poor handling of yams and 379 excessive exposure of yams to sunlight are the factors precipitating postharvest losses of 380 yams in the study area. The study recommends yam flour processing factory in the study 381 area, which will provide a ready yam market that will reduce postharvest losses of yams 382 and also increase the economic value of yams, both government and private investors 383 should take a business opportunity by building yam flour processing factory(s) in the 384 study area. 385
