Short Research Article

# Gene clone and bioinformatics analysis of subtilisin-like protease in Cucumis sativus

**Background:** Cucumber target leaf spot (TLS), caused by *Corynespora cassiicola*, is a serious disease in cucumber (*Cucumis sativus*) production worldwide. Therefore, cultivating new varieties of TLS resistance of *C. sativus* is an important goal of cucumber breeding. Previous studies have shown that subtilisin-like protease (SUBP) plays an important role in response to *C. Cassiicola* infection in resistant plants.

**Objective:** In this study, the full-length cDNA of the *CsSUBP* gene was cloned, and the prokaryotic expression vector was successfully constructed in order to study the effects of subtilisin. Futhermore, vital clues regarding *CsSUBP* gene involved in TLS resistance of *C. sativus* are gained from the bioinformatics assay.

**Method:** The *CsSUBP* gene was identified by sequencing with the intermediate vector pMD18 by designing specific primers and PCR amplification techniques. The prokaryotic expression vector pET30a-*CsSUBP* was further constructed and identified by colony PCR and *EcoR* V and *Sal*I double digestion.

**Result:** The primary structure of CsSUBP was predicted and analyzed by bioinformatics analysis. The results showed that CsSUBP was weakly acidic protein, N-terminal signal peptide region, including a Inhibitor_I9 domain domain which may be the primary disease resistance domain of the protein.

**Conclusion:** The pET30a-*CsSUBP* prokaryotic expression vector was constructed successfully. This study is convenient for the study of prokaryotic expression and its kinase activity.

## 1. INTRODUCTION

Cucumber (*Cucumis sativus*) is one of the largest vegetable crops in China. In recent years, cucumber target leaf spot (TLS), caused by *Corynespora cassiicola*, is a major disease in cucumber production[1]. At present, the prevention and treatment of TLS are mainly chemical control, chemical pesticide can be used to inhibit the activity of pathogens. However, *C. cassiicola* can easily mutate with environmental changes and develop resistance to various chemical pesticide, so it is difficult to prevent and eliminate the disease efficiently[2]. The best method for controlling the

disease in cucumber is the use of resistant cultivars, but few high resistant varieties of cucumber can enhance resistance of *C. cassiicola* at present. Therefore, understanding the molecular mechanisms and identifying the molecular components involved in the defense responses of the TLS resistant cucumber cultivars will provide a promising approach to restraining this disease.

In our previous study, a kind of subtilisin-like protease (SUBP) from resistant cucumber plants (Jingyou 38) after the fungus inoculation were explored using iTRAQ quantitative proteomics technique. It is speculated that the SUBP may play an important role in cucumber resistance to early invasion of *C. cassiicola*.

SUBP is a serine protease widely found in plants, bacteria, fungi, and parasites [3-8]. Such proteases have a typical Asp/Ser/His catalytic domain in structure. Studies have shown that it is closely related to the stability of the fungal phenotype and the pathogenicity of the pathogen. It plays an important immune stimulating role in the interaction between plants and pathogens [9]. SUBP is also involved in plant cell programmed cell death (PCD) processes[10]. A number of studies have demonstrated the role of SUBP in plant and pathogen interactions. For example, two subtilisin-like proteins, SAS-1 and SAS-2, in oat (Avena sativa) exhibit specific activity of mammalian caspase apoptosis protease and participate in the signal transduction of PCD during the non-affinity interaction of *oat-Cochliobolus victoriae*, thereby inducing HR production [11-12]. Overexpression of Arabidopsis subtilases gene *AtSBT3.3* activates downstream immune signaling and induces innate immune response in *Arabidopsis*[13].

In this study, the cDNA sequence of *CsSUBP* gene was cloned and the prokaryotic expression vector was constructed. The primary structure of CsSUBP was predicted and analyzed using bioinformatics analysis methods. On this basis, we can further explore the defense function and molecular mechanisms of SUBP against *C. cassiicola* in cucumber.

## 2. MATERIALS AND METHODS

### 2.1 Plant Materials

The cucumber varieties used in the experiments were Jinyou 38 (preliminary experiments showed that this variety was resistant to TLS), which were planted in a greenhouse at 28°C under 16:8 light/dark cycles.

### 2.2 Full-length cDNA cloning

Two candidate genes were screened through preliminary test on the basis of the proteomics analysis. The cDNA sequences of *CsSUBP* (A0A0A0K993) from resistant cucumber leaves were clone. The sequence of *CsSUBP* were aligned with cucumber genome database using the service provided by http://cucurbitgenomics.org/BLAST. The primers (table 1) were designed by using the DNAMAN. The PCR fragments amplified from the cDNAs were cloned into TA vectors pMD18-T and were sequenced.

**Table 1. *CsSUBP* gene primer sequences**

| Gene name | Primer sequence (5’ to 3 ’) |
|---|---|
| *CsSUBP-F* | GATATCATGTCCGGCCAATCCACAGCCCTG |
| *CsSUBP-R* | GTCGACCTAATGAAGCCTTGCTGCTCCTCCT |

### 2.3 Construction of recombinant prokaryotic expression vector pET30a-*CsSUBP*

Recombinant plasmid pMD18-T-*CsSUBP* and expression vector pET30a were digested by *EcoR* V and *Sal*Irespectively. The double-digested DNA fragment had the same sticky ends as the pET30a

vector backbone, and the two fragments were ligated into a complete recombinant plasmid using T4 ligase and ligated overnight at 16℃ and then trans-formed into E. coli DH5α competent cells, blue and white screening. Recombinant prokaryotic expression vector was identified by direct colony PCR. Recombinant prokaryotic expression vector pET30a-*CsSUBP* plasmid was extracted and the product was digested by *EcoR V* and *SalI* respectively. It was digested for 3 h at 37℃ in a constant temperature metal bath and electrophoresed on a 1.5% agarose gel. Plasmids with positive clones were sent for bioinformatics sequencing.

**2.4 Bioinformatics analysis**

The specific bioinformatics [14-17] analysis contents and tools used are as follows see table 2.

**Table 2 Bioinformatics analysis content and Tools website**

| Analyze the content | Name of software | Bioinformatics Analysis Tools Website |
|---|---|---|
| Primary structure | ProtParam | http://web.expasy.org/protparam/ |
| Secondary structure | SOPMA | http://npsa-pbil.ibcp.fr/cgi-bin/npsa_automat.pl?page=/NPSA/npsa_sopma.html |
| Hydrophobicity | ProtScale | http://web.expasy.org/protscale/ |
| Signal peptide | SignalP 4.0 | http://www.cbs.dtu.dk/services/SignalP/ |
| Functional domains | SMART | http://smart.embl-heidelberg.de/ |

## 3. RESULTS

### 3.1 Amplification of *CsSUBP*

The reverse transcription of cDNA was used as the template. PCR amplification product was subjected to 1.5% agarose gel electrophoresis and a fragment of approximately 282 bp was obtained as expected (Fig.1)

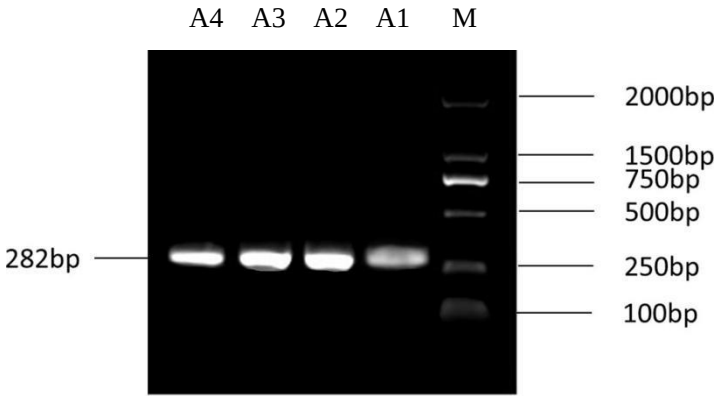

**Fig. 1 Electrophoresis profile of PCR products of CsSUBP Gene. A1-A4: *CsSUBP* PCR amplification products; M: DL2000 DNA Marker**

### 3.2 Construction of Prokaryotic Expression Vector

To construct the prokaryotic expression vector, we recycle the small fragments of pMD18-T-*CsSUBP* (Fig. 2, 3) and large fragments of pET30a plasmid after double digest with *EcoR* V and *Sal*I. The colony PCR products of recombinant plasmid pET30a-*CsSUBP* via agarose gel electrophoresis analysis showed 282 bp of the target gene band (Fig.4, 5). Sequencing results showed that the gene fragments was consistent with the target gene sequence in GenBank (Fig. 6).

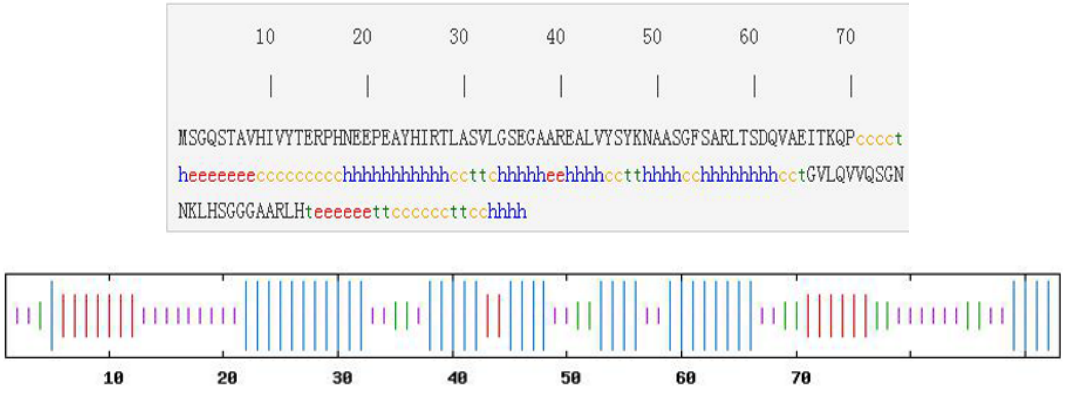
### 3.3 Bioinformatics Analysis of CsSUBP proteins

Some information about the CsSUBP are obtained by some online tools (shown in table2). The protein molecular weight is 23146.02, chemical formula is $C_{834}H_{1388}N_{282}O_{348}S_{69}$, isoelectric point (pI) is 5.28. It is weakly acidic and hydrophobic average coefficient is 0.794. It is speculated that CsSUBP maybe a hydrophobic protein (shown in Fig 8). Neither signal peptide nor transmembrane region is found in the CsSUBP (shown in Fig 9).

Secondary structure of CsSUBP is analysed by SOPMA. The result showed that CsSUBP consists of 39.78% alpha helix (h), 16.13% extended strand (e), 11.83% beta turn (t) and 32.26% random coil (c)(Fig.7 and Table 3).



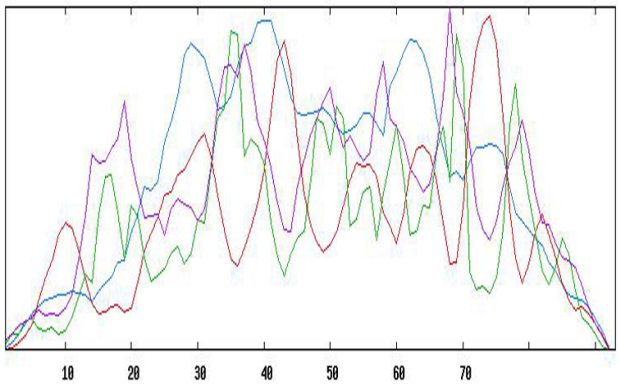


**Fig. 7 The secondary structure of CsSUBP protein. h: Alpha helix; t: Beta turn; e: Extended strand; c: Random coil**

**Table 3 Prediction the secondary structure of CsSUBP protein**

| Name | Number | Percentage |
|---|---|---|
| Alpha helix | 37 | 39.78% |
| $3_{10}$ helix | 0 | 0.00% |
| Pi helix | 0 | 0.00% |
| Beta bridge | 0 | 0.00% |
| Extended strand | 15 | 16.13% |
| Beta turn | 11 | 11.83% |
| Bend region | 0 | 0.00% |
| Random coil | 30 | 32.26% |
| Ambigous states | 0 | 0.00% |
| Other states | 0 | 0.00% |

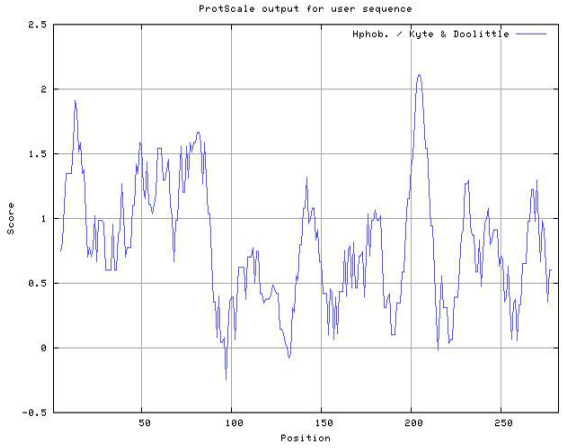

**Fig. 8 Prediction the hydrophobicity of CsSUBP protein**

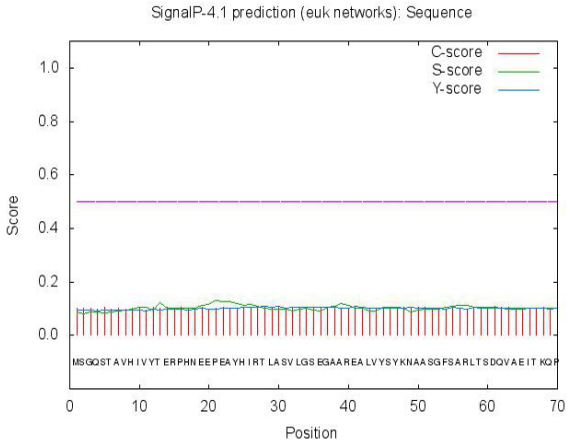

**Fig. 9 Prediction the signal peptide of CsSUBP protein**

A major functional domains of *CsSUBP*-encoded proteins is found by SMART analysis. The results are shown in Table 4.

**Table 4 Functional domain analysis of *CsSUBP*-encoded proteins**

| Name | Position | E-value |
|---|---|---|
| Inhibitor_I9 domain | 8(Starting site)-84(Termination site) | 4.8e-15 |

Inhibitor_I9 domain, which belongs to a member of the MEROPS family of protease inhibitors I9, a protease pro-peptide inhibitor (sometimes referred to as an activated peptide) that regulates the folding and activity of the proenzyme or zymogen. The anterior segment extends into the enzyme moiety and shields the substrate binding site, thereby promotes enzyme inhibition. Although it often has lower sequence identity, several such propeptides have similar topologies. The propeptide region has an open-loop, sandwich-like anti-parallel α/ β, it also has two α-helices and four β-strands with a 2x (β/α/β) topology.

CsSUBP also belongs to the N-terminal propeptide domain of the meropsis family S8A, a subtilisin peptidase. The use of the subtilisin propeptide as a chaperone helps to fold the mature peptidase. The

propeptide is removed by proteolytic cleavage to remove the activating enzyme.

## 4. CONCLUSION

We have successfully amplified and purified of *CsSUBP* gene in cucumber coding sequence, and constructed the recombinant prokaryotic expression vector pET30a-*CsSUBP*. Bioinformatics analysis shows that CsSUBP belongs to the hydrophobic protein and has no signal peptide at the N-terminus. It contains a functional domain . Its protein chemical formula is $C_{834}H_{1388}N_{282}O_{348}S_{69}$ , an isoelectric point (PI) is 5.28 and a molecular weight is 23146.02. Our study is a preparation for revealing the functions and mechanisms of CsSUBP against *C. cassiicola* in cucumber.
