Original Research Article

Prevalence of *Selenomonas noxia* among pediatric and orthodontic patients

Abstract

Objectives: Pediatric patients face many challenges to oral and periodontal health, including the placement of fixed orthodontic appliances during adolescence. One of the more recently identified periodontal pathogens is the organism *Selenomonas noxia* or *S. noxia*. Due to the paucity of evidence regarding the oral prevalence of *S. noxia* and the lack of evidence regarding the prevalence among pediatric orthodontic patients, the main objective of this project was to evaluate the oral prevalence in a dental school setting.

Methods: Using an existing saliva repository, twenty five (n=25) orthodontic samples were selected from patients between the ages of 13 – 24 with twenty five (n=25) age-matched non-orthodontic samples. DNA isolation was performed and screened with primers specific for *S. noxia*.

Results: Screening of each DNA derived from each saliva sample for *S. noxia* revealed the presence of this pathogen in a subset of the study population. More specifically, the majority of samples screened (60% or n=30/50) did not harbor DNA for this organism. Most of the *S. noxia*-positive samples were derived from adults (65% or n=13/20) with more females (60%) than males, which were nearly equally divided among Orthodontic and non-Orthodontic patients.

Conclusions: This study provides novel information regarding the oral prevalence of *S. noxia* among both pediatric and young adult populations, with and without orthodontic brackets. These findings demonstrate that higher percentages of adults than pediatric patients harbor this organism, which does not appear strongly correlated with orthodontic treatment. These data add to the growing body of evidence that may suggest the presence of this organism may be associated with many additional factors that influence oral health and disease.

Key words: *Selenomonas noxia*, periodontal disease, orthodontic treatment, saliva screening.

Abbreviations: Office for the Protection of Research Subjects (OPRS), Institutional Review Board (IRB), deoxyribonucleic acid (DNA), polymerase chain reaction (PCR), American Type Culture Collection (ATCC), Glyceraldehyde- 3- phosphate dehydrogenase (GAPDH), limit of detection (LOD).

Introduction

Pediatric patients face many challenges to oral and periodontal health, including the placement of fixed orthodontic appliances during adolescence [1,2]. Although many studies have evaluated the effectiveness of various interventions on the outcomes of caries and periodontal disease, fewer of these studies have focused specifically on particular pathogens [3,4]. The question then remains whether these previously identified periodontal pathogens are more prevalent during orthodontic treatment [5,6].

One of the more recently identified periodontal pathogens is the organism *Selenomonas noxia* or *S. noxia* [7,8]. *Selenomonas* species are gram-negative obligate anaerobic microbes, some of which have been identified as periodontal pathogens [9-11]. These organisms, including *S. noxia*, have been identified in patients with severe or aggressive periodontitis [12-14].

Interestingly, this organism has recently been associated with other health conditions, including obesity and arthritis-induced bone loss [15,16]. However, despite these many disease associations – few studies have evaluated the prevalence of this organism [17,18]. Due to the development of a rapid screening assay that can function using DNA isolated from saliva, recent efforts from this group have attempted to assess prevalence among a dental school population – although no evaluation of pediatric orthodontic patients has yet been attempted.

Due to the paucity of evidence regarding the oral prevalence of *S. noxia* and the lack of evidence regarding the prevalence among pediatric orthodontic patients, the main objective of this project was to evaluate the oral prevalence using saliva samples derived from these patient populations in a dental school setting.

Methods

Study approval

This retrospective study was reviewed by the Office for the Protection of Research Subjects (OPRS) and the Institutional Review Board (IRB) at the University of Nevada, Las Vegas (UNLV). The exemption for this study OPRS#880427-1 was titled "The prevalence of oral microbes in saliva from the UNLV School of Dental Medicine pediatric and adult clinical population.

Sample selection

The original protocol for saliva collection involved Informed Consent (adult) and Pediatric Assent (pediatric) prior to unstimulated saliva collection. Samples were obtained in sterile 50 mL collection tubes and transported to the biomedical laboratory for storage (-80C) and future analysis. Each sample was assigned a randomly generated, non-duplicated identifier that prevented any person from directly or indirectly linking a specific sample to any patient identifying information. Limited demographic information was concurrently collected, which provided Sex, Age, Race or Ethnicity (if voluntarily provided) and whether or not the patient had orthodontic brackets.

For this study, a total of fifty (n=50) samples were selected for screening. This study population involved twenty five (n=25) orthodontic samples selected from patients between the ages of 12 – 24 with twenty five (n=25) age-matched non-orthodontic samples.

DNA isolation

The selected samples were thawed for subsequent DNA isolation using the GenomicPrep DNA isolation kit using the protocol outlined by the manufacturer, as previously described [19,20]. The DNA from each sample was then analyzed for purity and concentration using a NanoDrop spectrophotometer at absorbances of 230, 260 and 280 nm. Samples with a concentration > 1 ng/uL and A260:A280 ratio above 1.55 were then screened for *S. noxia*.

PCR screening

In brief, qPCR used initial incubation of 50C for 120 seconds, followed by denaturation at 95C for ten minutes and 40 cycles, consisting of 95C for 15 seconds and 60CC for 60 seconds. Positive control human glyceraldehyde 3-phosphate dehydrogenase (GAPDH) and standards

were derived from American Type Culture Collection (ATCC) *S. noxia* reference strains ATCC-43541, -51893, and -700225), as previously described [18,19].

Positive control:

Glyceraldehyde- 3- phosphate dehydrogenase (GAPDH)

GAPDH 5'-ATCTTCCAGGAGCGAGATCC-3' (sense); 20 nt; 55% GC; Tm=66C

GAPDH 5'-ACCACTGACACGTTGGCAGT-3' (antisense); 20 nt; 55%GC; Tm=70C

Optimal PCR Tm: 65C

Forward primer- SNF1, TCTGGGCTACACACGTACTACAATG (25 bp)

Reverse primer- SNR1, GCCTGCAATCCGAACTGAGA (20 bp)

SnP[6 ~ FAM]CAGAGGGCAGCGAGAGAGTGATCTTAAGC [TAMRA]

The selected probe (SnP) was labeled with the reporter dye 6-carboxyfluorescein (FAM) at the 5'-end and with the reporter dye tetramethyl-6-carboxyrhodamine (TAMRA) at the 3'-end.

Results

The demographic analysis of the study sample (n=50) was performed using the clinic population for reference (Table 1). These data demonstrated that the study sample was comprised of approximately half females (52%) and half males (48%), which was not significantly different than the overall percentages in the clinic population (50.9% and 49.1%, respectively), p=0.4865. However, the proportion of samples from minority patients in the study sample (72%) was significantly higher than the percentage from the clinic population (58.6%), p=0.0001. The majority of these patients were Hispanic in both the study sample (56%) and the clinic (35.9%).

The samples derived from pediatric patients ranged in age from 12 – 17 years with an average age of 13.25 years, which is slightly older than the pediatric clinic population average of 10.14 years. The average age of the adult samples was 21.57 years with a range of 18 – 24 years, which is much younger than the overall clinic population average of 52.3 years.

Table 1. Demographic analysis of sample study.

	Study sample (n=50)	Clinic population	Statistical analysis
Sex			
Female	52.0% (n=26)	50.9%	$\chi 2$=0.484, d.f.=1
Male	48.0% (n=24)	49.1%	p=0.4865
Race / Ethnicity			
White	28.0% (n=14)	41.4%	$\chi 2$=74.014, d.f.=1
Minority	72.0% (n=36)	58.6%	p=0.0001
Hispanic	56.0% (n=28)	35.9%	
Black	8.0% (n=4)	13.1%	
Asian / Other	8.0% (n=4)	9.6%	
Age			
Pediatric (n-26)	Range: 12 – 17 yrs. Ave.=15.25 yrs.	Range: 0 – 17 yrs. Ave.=10.14 yrs.	
Adult (n=24)	Range: 18 – 26 yrs. Ave.=21.57 yrs.	Range: 18 – 91 yrs. Ave.=52.3 yrs.	

Each of the samples was then processed to extract DNA for the subsequent screening (Table 2). These data demonstrated that DNA was successfully extracted from all samples (n=50) resulting in a yield of 100 (n=50/50), which approximates the range estimated by the manufacturer protocol (90-95%). The concentration of the samples was approximately 500 ng/uL, which was similar from both the pediatric (502.1 ng/uL) and adult (493.2 ng/uL) patient samples. The purity of the DNA isolates measured by the absorbance ratio of A260 nm and A280 nm demonstrated that all samples were of sufficient quality to proceed with the PCR screening.

Table 2. DNA isolation and study sample analysis.

	DNA concentration	DNA purity	Recovery/yield
Study sample	499.52 ng/uL +/- 70.3	A260:A280=1.72	100% (n=50)
Pediatric samples	502.1 ng/uL	A260:A280=1.71	
Adult samples	493.2 ng/uL	A260:A280=1.74	
Manufacturer range	100 – 1000 ng/uL	1.70-2.00	90-95%

Screening of each DNA derived from each saliva sample for *S. noxia* revealed the presence of this pathogen in a subset of the study population (Figure 1). More specifically, the majority of samples screened (60% or n=30/50) did not harbor DNA for this organism. In addition, most of the *S. noxia*-positive samples were derived from adult patients (65% or n=13/20). Finally, the majority of positive samples appeared in the 14-17 age range for pediatric patients and the younger age ranges 18 – 25 for the adult patients.

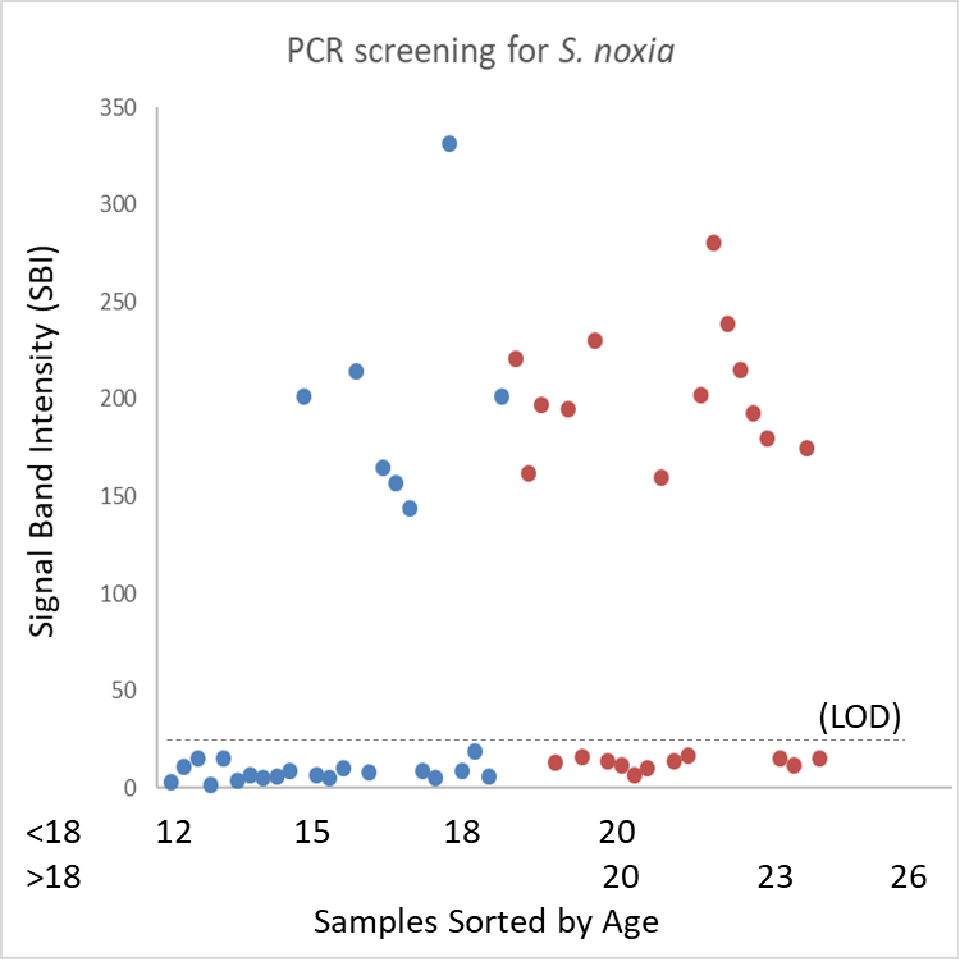

Figure 1. PCR screening of samples for *S. noxia*. The majority of samples were S. noxia-negative (60%, n=30/50). The *S. noxia*-negative samples were nearly equally divided among females and males, as well as orthodontic and non-orthodontic patients. However, the majority of *S. noxia*-positive samples above the reliable limit of detection (LOD) were derived from adult (65% or n=13/20) versus pediatric (35% or n=7/20) patients.

To more thoroughly evaluate these results, a demographic analysis of the *S. noxia*-positive and *S. noxia*-negative samples was performed (Table 3). This analysis revealed that the majority of positive samples were derived from adult patients (65%) rather than pediatric patient samples (35%). In addition, there was a slightly higher proportion of females with positive samples (60%) than males (40%). Slightly less than half of the positive samples came from Orthodontic patients (45%).

However, the analysis of negative samples revealed that most of these samples were derived from pediatric patients (63.3%). In addition, slightly more than half were also Orthodontic patients (53.3%). Finally, slightly more than half of the negative samples were derived from male patients (53.3%).

Table 3. Demographic analysis of *S. noxia*-positive and *S. noxia*-negative samples.

	***S. noxia*-positive (n=20)**	***S. noxia*-negative (n=30)**
Sex		
Female	60.0% (n=12)	46.7% (n=14)
Male	40% (n=8)	53.3% (n=16)
Age status		
Pediatric	35.0% (n=7)	63.3% (n=19)
Adult	65.0% (n=13)	36.7% (n=11_
Clinic status		
Orthodontic	45.0% (n=9)	53.3% (n=16)
Non-Orthodontic	55.0% (n=11)	46.7% (n=14)

Discussion

Due to the paucity of evidence regarding the oral prevalence of *S. noxia* and the lack of evidence regarding the prevalence among pediatric orthodontic patients, the main objective of this project was to evaluate the oral prevalence using saliva samples. This retrospective study was successful in identifying existing saliva samples from dental school patient populations, isolating DNA from each sample and subsequently screening for *S. noxia* using PCR.

These results have some similarities and differences with recent studies from this institution. For example, one recent study found no *S. noxia* among 54 pediatric patient samples – although the average ages of those patients were significantly younger (9.25 yrs.) than patients in the current study (15.25 yrs.) [19]. This may suggest that this organism (like many other periodontal organisms) appears in greater numbers during the onset of puberty and adolescence [11-13]. In addition, the lack of association with orthodontic treatment may also suggest the presence of this organism may not be strongly correlated with these procedures and that other factors, such as hormone levels or oral hygiene practices may, in fact, be stronger predictors [4-6].

Although this study provides novel information regarding the oral prevalence of this organism in these patient populations, there are some limitation inherent to this type of study that should also be considered in context. First, this was a retrospective study of previously collected salivary samples. Although every effort was made to reduce research bias of any kind, many types of bias exist in cross sectional (one-time sampling) studies – including the lack of temporal (before and after) information regarding patient health and microbial levels. In addition, the willingness of patients to participate in any study (pediatric or adult) may also lead to selection bias that could also significantly influence the results from this type of study. Finally, the lack of other health information (such as weight, body mass index, or neck circumference) was not available, with some studies suggesting that *S. noxia* may be more strongly associated with obesity and periodontal disease than periodontal disease alone [21,22].

Conclusions

This study provides novel information regarding the oral prevalence of *S. noxia* among both pediatric and young adult populations, with and without orthodontic brackets. These findings demonstrate that higher percentages of adults than pediatric patients harbor this organism, which does not appear strongly correlated with orthodontic treatment. These data add to the growing body of evidence that may suggest the presence of this organism may be associated with many additional factors that influence oral health and disease.
