

Optimization of Foam-Mat Drying Process of Watermelon Pulp Using Response Surface Methodology

ABSTRACT

Introduction: Foam mat drying involves the change of agricultural material from a high moisture content level to a stable foam which is achieved by moisture reduction mechanism.

Aim: In this study, foam-mat drying process of watermelon was optimized using response surface methodology. Foaming conditions (Carboxyl methyl cellulose and egg albumen) and the drying system parameters (air velocity and air temperature) were optimized using response surface methodology.

Methodology: To evaluate the drying behaviour, the drying experiment was designed using design expert software using a central composite design setting variable of drying temperature (60 °C – 80 °C), air velocity (0.5 m/s – 2 m/s), carboxyl methyl cellulose (0.5 % - 2.5 %), egg albumen (5 % - 15 %). Twenty-two runs of the experiment were performed using different levels of variables combinations. Based on the statistical tests performed, the best model that described each response was selected using a polynomial analysis.

Results: The optimized values for the drying characteristics was 25.07 KJ/mol for activation energy, $1.7345E-10 \text{ m}^2/\text{s}$ for effective diffusivity, 29.019 % wet-basis for moisture content, $0.742 \text{ g}/\text{cm}^3$ for foam density and approximately 540 minutes (9hrs) for the drying time.

Conclusion: The study of the foam-mat drying of watermelon pulp revealed that the inlet temperature, air velocity, CMC and egg albumen has a significant effect on its drying characteristics.

Keywords: Watermelon pulp, foam-mat drying, optimization, response surface methodology, activation energy

27 **1 Introduction**

28 Foam mat drying involves the transformation of biological material from a liquid to a stable
29 foam which is accomplished by air drying [1]. Azizpour et al. [2] reported that foam mat drying
30 dates back to 1917. Foam mat drying which is an example of a novel drying technique [3] has
31 received attention by its characterization through faster drying, and drying of material that
32 contain high moisture content [2]. Foam mat drying can be used in the removal of moisture in
33 juice, milk, fruits, beverages, jams [4]. Application of foam mat drying can be extended to the
34 large-scale production of fruit powders

35 Watermelon (*Citrullus lanatus*) belongs to the family Cucurbitaceae and in the same family with
36 cucumber and pumpkin. There are more than 100 varieties of watermelon ranging in weight from
37 less than 1.4 kg to more than 32 kg and may be round or oblong in shape. It has smooth skin and
38 may vary in color from light green to dark green [5]. Watermelon contains 91% water and 7% of
39 carbohydrates. It is rich in lycopene a very powerful antioxidant, and also in citrulline [6]. [7]
40 made a report that watermelon is a valued source of natural antioxidants with special reference to
41 lycopene, ascorbic acid, and citrulline and these functional ingredients act as protection against
42 chronic health problems like cancer insurgence and cardiovascular disorders. Many research
43 works agreed with that fact that watermelon contains two health benefit component that cannot
44 be ignored. Fruits have been said to be a major source of concentrated natural components that
45 help in maintaining human health; Lycopene, a red pigment of the carotenoid class found in only
46 a few fruits and vegetables, is a powerful oxygen radical scavenger and highly effective
47 antioxidant. A high dietary intake of tomatoes, rich in lycopene content, is associated with a
48 lower risk of certain cancers, primarily of the prostate [8]

49 Citrulline is described by [8] as a non-essential amino acid, its medication through oral method
50 to children and adolescents with sickle cell disease resulted in improvement in symptoms and
51 raised plasma arginine levels. It was concluded that watermelon rind is a rich source of amino
52 acid and also might produce a good product from agricultural waste.

53 This research work is focused on optimization of the drying characteristics of foam dried
54 watermelon as a function of drying system parameters (temperature and air velocity) and
55 structural parameters (foaming and stabilizing agent). Response surface methodology (RSM); a
56 collection of mathematical and statistical technique that are useful for modeling and analysis of

57 problems in which the response is influenced by several variables. The most extensive
58 applications of RSM are in the particular situations where several input variables potentially
59 influence some performance measure or quality characteristic of the process [9].

60 **2 Materials and methods**

61 The experiment to accomplish the desired objectives was performed in the Department of
62 Agricultural and Environmental Engineering of Federal University of Technology, Akure.

63 **2.1 Selection and sample preparation**

64 The watermelon fruit used for this study were purchased in local retail store around the south
65 gate of the Federal University of Technology, Akure. The fruits were wash and store until use.
66 The watermelon rind was removed, sliced into cubes and the seeds were removed. The fruits
67 were blended into juice using Binatone blending machine.

68 **2.1.1 Foam treatment**

69 The foamed watermelon concentrate was prepared by giving foaming treatment to the prepared
70 concentrated juice by adding different levels of foaming agents, foaming stabilizer. The foaming
71 agent and foaming stabilizer was added to watermelon concentrate at room temperature. The
72 formation of foam was formed by whipping with a mixer. The foaming agent: Egg albumen (5-
73 15 %), foaming stabilizer: Methylcellulose (0.5-2.5 %) and whipping time: 3-15 minutes. The
74 foamed watermelon concentrates were prepared by varying the levels of foaming agent and the
75 foaming stabilizer.

76 **2.2 Experimental design for optimization of foamed watermelon pulp**

77 The central composite experimental design was selected for the optimization of process variables
78 i.e. egg albumen, carboxyl methylcellulose, air velocity, and drying temperature using Response
79 surface methodology. Response surface methodology or RSM; a collection of mathematical and
80 statistical technique that are useful for modeling and analysis of problems in which the response
81 is influenced by several variables. The most extensive applications of RSM are in the particular
82 situations where several input variables potentially influence some performance measure or
83 quality characteristic of the process [9]. The design experiment runs were generated by using a
84 central composite design using a variable of air velocity, temperature, egg albumen as a foaming

85 agent and carboxyl methyl cellulose as the stabilizing agent and giving a response variable of
86 Activation Energy, Moisture Diffusivity, foam density, drying time and Final moisture

87 **2.2.1 Determination of foam density**

88 The density of the foamed watermelon pulp was determined in terms of mass per volume
89 (g/cm^3). The density was determined by measuring the foam volume in a cylindrical beaker and
90 measuring the mass with the use of weighing balance.

$$91 \quad \text{Foam density } \rho = \frac{\text{mass}}{\text{volume}} \text{ g}/\text{cm}^3 \quad (2.1)$$

92 **2.2.2 Determination of the drying parameter**

93 The experiment sample was spread on an aluminum foil and placed in a mechanical dryer. The
94 weight of the sample weight of each sample was checked every half an hour to determined
95 drying rate and other drying parameters.

96 Table 2.1: Nomenclature of drying parameters

Abbreviations	Full form
x^2	Reduced chi-square
a, b, c, n	Empirical constants in drying models
CMC	Carboxyl Methyl Cellulose
D_{eff}	Effective moisture diffusivity, m^2/s
K	Drying constant
L	The thickness of foam mat, m
M_i	Initial moisture content
M_t	Moisture content at time t, kg moisture
M_e	Equilibrium moisture content, kg moisture
M_o	Initial moisture content, kg moisture
MR	Dimensionless moisture ratio
N	Number of observations

R^2	Coefficient of determination
$RMSE$	Root mean square error
MBE	Mean biased error
t	Drying time, h
Z	Number of drying constant
EA	Egg Albumen

97

98 **2.2.3 Determination of drying rate (DR)**

99 The drying rate is one of the important parameters that help in the understanding of drying
100 characteristics of a material. The drying rate is calculated using expression described by Salahi et
101 al. [10]

102
$$DR = \frac{M_t - M_{t+\Delta t}}{\Delta t} \quad (2.2)$$

103 where $M_{t+\Delta t}$ is moisture content at $t + \Delta t$ (kg water/kg dry solid), t is the time (min) and Δt is time
104 difference (min).

105 **2.2.4 Determination of moisture ratio**

106 The moisture content of the samples was expressed in term of moisture ratio (MR) using the
107 expression described by salahi et al. [10]

108
$$MR = \frac{M_t - M_e}{M_i - M_e} \quad (2.3)$$

109 **2.2.5 Determination of moisture diffusivity**

110 Fick's diffusion equation was used for calculation of effective diffusivity as described by Wilson
111 *et al.* [11]

112
$$MR = 8/\pi^2 \exp\left(\frac{-\pi^2 D_{eff} t}{4L^2}\right) \quad (2.4)$$

113 Which can be rewritten as

114
$$D_{eff} = \frac{\ln MR - \ln \frac{8}{\pi^2}}{\frac{\pi^2 t}{4L^2}} \quad (2.5)$$

115 The slope (K_o) is calculated by plotting $\ln(MR)$ against time to determine the effective diffusivity
116 for different temperatures.

$$117 \quad K_o = \left(\frac{\pi^2 D_{eff}}{4L^2} \right) \quad (2.6)$$

118 **2.2.6 Determination of activation energy**

119 The relationship between the diffusion coefficient with the temperature can often be described by
120 the Arrhenius-type relationship Equation as described by Azizpour et al. [12] in equation 2.7

$$121 \quad D_{eff} = D_o \exp\left(-\frac{E_a}{RT}\right) \quad (2.7)$$

122 where D_o is the constant in Arrhenius equation ($m^2 s^{-1}$); E_a is the activation energy ($KJ mol^{-1}$); R
123 is the universal gas constant ($kJ mol^{-1} K^{-1}$). It can be rearranged in the form of:

$$124 \quad \ln(D_{eff}) = \ln(D_o) - \frac{E_a}{RT} \quad (2.8)$$

125 The activation energy was calculated by plotting the $\ln(D_{eff})$ against the reciprocal of absolute
126 temperature ($1/T$)

127 **3 Results and Discussions**

128 **3.1 Model fitting**

129 The central composite design (CCD) data were analyzed using multiple regression analysis and
130 the correlation between the independent variables of foam mat drying *viz.*, Temperature (60-80
131 °C), air velocity (0.5-2.5 m/s) carboxyl methyl cellulose (0.5-2.5 %) and egg albumen (5-15 %) and
132 dependent variables such as activation energy, effective diffusivity, moisture content, foam
133 density and drying time. After the analysis, a polynomial relationship was developed between the
134 dependent and independent variable.

135 **3.1.1 Model equations**

136 From equation 3.1, the coefficients of the first order terms variables indicated that the activation
137 energy increased with the increased in inlet air temperature, decreased in air velocity, increased
138 in CMC, decreased in egg albumen and increased in combination of both CMC and egg albumen
139 concentration.

140 From equation 3.2, the coefficients of the first order terms variables indicated that the effective
141 diffusivity increased with increased in temperature, decreased in air velocity, decreased in CMC,
142 decreased in egg albumen.

143 From equation 3.3, the coefficients of the quadratic equation variables indicated that the moisture
144 content increased with decreased in temperature, increased in air velocity, increased in CMC,
145 increased in egg albumen and decreased with combination of CMC and egg albumen.

146 From equation 3.5, the coefficients of the linear equation indicated that the drying time increased
147 with increase in temperature, increase in air velocity, decrease in CMC and egg albumen
148 concentration.

$$149 \text{ Activation energy} = 22.15 + 1.17A - 0.8808B + 0.4647C - 0.3717D - 1.43AB + \\ 150 \quad \quad \quad 0.9196CD \quad \quad \quad (3.1)$$

$$151 \text{ Effective diffusivity} = 9.6267E - 11 + 2.636E - 11A - 1.442E - 11B - 1.17E - \\ 152 \quad 11C - 1.899E - 11D + 1.657E - 11AB + 1.395E - 11CD \quad (3.2)$$

$$153 \text{ Moisture content} = 40.52 - 9.86A + 1.15B + 2.44C + 8.40D + 1.35AB - 2.90CD \quad (3.3)$$

$$154 \text{ Foam density} = 0.7425 \quad (3.4)$$

$$155 \text{ Drying time} = 684 - 36.12A + 47.8B - 32.98C - 2.86D + 51.77AB + 2.77CD \quad (3.5)$$

156 Where

157 A = Temperature

158 B = Air velocity

159 C = Carboxyl methylcellulose concentration

160 D = Egg albumen

161 **3.2 Optimization of drying characteristics of watermelon pulp**

162 Numeric optimizations were carried out for the drying system parameters and the structural
163 parameters of foam dried watermelon pulp. The desirability of the independent variables and the
164 dependent variables was summarized in the table 3.1. The goal was to put the dependent factors;
165 temperature, air velocity, CMC and egg albumen in range. The independent factors; effective
166 diffusivity and foam density to be maximized. Activation energy, moisture content and drying
167 time to be minimized. The optimum conditions for the independent variables were found to be
168 temperature 77.42 °C, air velocity 0.5 m/s, carboxyl methylcellulose of 0.5 %, Egg albumen 5 %

169 for achieving minimized activation energy of 25.07 KJ/mol, maximized effective diffusivity of
 170 $1.74345E-10 \text{ m}^2/\text{s}$, minimized moisture content to be 29.19% wet-basis, maximized foam density
 171 of 0.742 g/cm^3 , minimized drying time of 9hrs with a desirability of 70.2%. The effective
 172 diffusivity of the foam-mat dried watermelon increases with temperature as shown on the model
 173 plot. This behavior is also observed in foam mat drying of watermelon pulp by Wilson et al. [11].
 174 The moisture content of foam dried watermelon reduces with increasing temperature and at a
 175 range of air velocity of 1.1 – 1.4 m/s. keeping the carboxyl methyl cellulose and egg albumen at
 176 1.5% and 10% respectively. This may be due to the generation of high hot air during drying,
 177 which might have trapped the moist air that was found in the fed product and it might have
 178 reduced the moisture content to a greater extent which was also reported by Jaya and Das [13].
 179 The drying time of the foam dried watermelon reduces with increasing temperature and reducing
 180 air velocity. The drying time 600 minutes (10hrs) was recorded between a temperature of $74 \text{ }^\circ\text{C}$
 181 – $80 \text{ }^\circ\text{C}$ and an air velocity of 0.5 m/s and 8 m/s. moisture content reduces with a decrease in egg
 182 albumen concentration but increases with increases in carboxyl methylcellulose concentration.
 183 Maciel *et al.* [14] also reported that moisture loss was faster in samples containing higher
 184 albumen concentration.

185 **Table 3.1: Optimization Goal Table**

Name	Goal	Lower Limit	Upper Limit	Lower Weight	Upper Weight	Importance
A:Temperature	is in range	60	80	1	1	3

201 4 Conclusion

202 The foam-mat drying of watermelon pulp was successfully carried out using a central composite
203 design followed by response surface methodology. The optimum process conditions of foam-mat
204 drying of watermelon pulp were activation energy of 25.07 KJ/mol, effective diffusivity of 1.73
205 $\times 10^{-10}$ m²/s, the moisture content of 29.02 % (wet basis), a foam density of 0.74 g/cm³, drying
206 time of 540 minutes. A polynomial analysis was carried out, were quadratic model best described
207 the activation energy, effective diffusivity, moisture content. mean model best described the
208 foam density, whilst linear and 2FI model described the drying time. The study of the foam-mat
209 drying of watermelon pulp revealed that the inlet temperature, air velocity, CMC and egg
210 albumen concentration has a significant effect on the drying characteristics of the process.
