1 2	Comparative study of 50% Trichloroacetic acid solution versus 10% Potassium hydroxide solution in the treatment of plane warts
3	
4	Short title: Trichloroacetic acid versus Potassium hydroxide in plane warts therapy
5	
6	Abstract
7	Background: Warts are very common disorders. Plane warts are caused by Human Papilloma
8	Virus (HPV) occurring mostly in children and young adults. Among the treatment modalities,
9	topical application of trichloroacetic acid (TCA) is age old. Potassium hydroxide (KOH) has a
10	keratolytic effect on virus-infected cells.
11 12	Aims: To compare the safety and efficacy of topical 10% KOH solution with 50% TCA solution in the treatment of plane warts.
13	Materials and Methods: Sixty-four consecutive patients with plane warts were randomly
14	assigned into two groups of thirty-two patients. Group A received 10% KOH solution and group
15	B received 50% TCA solution once weekly until the complete clearance of warts in a maximum
16	period of 12 weeks.
17	Results: In group under treatment with 10% KOH, 24 patients (75.0%) complete response, 5
18	patients (15.6%) moderate response, 2 patients (6.3%) mild response, and 1 patient (3.1%) had
19	no response. In group under treatment with 50% TCA, 28 patients (87.5%) showed complete
20	response, 2 patients (6.3%) moderate response, 2 patients (6.3%) mild response. Statistically no
21	significant difference was found between the therapeutic response to 10% KOH and 50% TCA
22	(P=0.41).
23 24	Conclusion: 10% KOH was found to be equally effective in the treatment of plane warts compared to 50% TCA with the advantage of fewer side effects.
25	Keywords: Plane warts, Potassium hydroxide, Trichloroacetic acid, therapy
26	
27	
28	Introduction
29	Warts are caused by infection of keratinocytes by human papillomavirus (HPV). The incidence
30	increases during childhood to reach a peak in adolescence and early adulthood then declines
31	rapidly through the 20s and more gradually thereafter [1]. Its prevalence among children has
JT	rapiery infough the 20s and more graduary increation [1]. Its prevalence among enfluten has

reported to be between 2-20% in different communities [2]. Verruca plana or plane warts are
caused by HPV types 3, 10, 28, and 41, occurring mostly in children and young adults. Sites of
predilection are face, back of hands, and the shins. They are 2-4 mm flat-topped papules and are
erythematous or brown-colored on pale skin and hypopigmented on darker skin [3]. They have
the tendency to koebnerize, especially in the children [3].

Diagnosis and treatment of the disease is very important in terms of beauty issues and preventing 37 the proliferation of warts [4]. Today, many different treatments are used to eliminate warts, which 38 include two major groups of medical treatments and surgical procedures [5]. Medical treatments 39 due to the need for continuous use, and skin sensitivities and side effects are not widely popular 40 among patients [4,5]. In addition, surgical treatments have reduced efficacy due to complications 41 such as scars and the possibility of recurrence of warts [4,5]. There are many modalities for the 42 treatment of plane warts that includes topical salicylic acid, glycolic acid, 5-fluorouracil, 43 isotretinoin gel, topical zinc sulfate solution, citric acid, trichloroacetic acid (TCA), bacillus 44 45 Calmette-Guérin immunotherapy, curettage/electrodessication, and cryotherapy [6-10]. Most treatments focus primarily on the destruction or removal of visible lesions or on the induction of 46 cytotoxicity against the infected cell. Among these agents, TCA and potassium hydroxide (KOH) 47 are less stimulant and cause less scar [11, 12]. 48

TCA is a topical destructive agent and causes hydrolysis of cellular proteins leading to cell death.
It is effective in treating common, cervical, genital, and anal warts in the concentrations of 7080% and has response rates comparable to cryotherapy [11, 12]. Low concentrations (10-30%)
are used for the treatment of common warts and superficial peeling. The advantage is the
complete lack of systemic toxicity; however, a few local effects such as pain, burning,
hyperpigmentation, and rarely scar formation may occur [13].

Potassium hydroxide is a strong metallic base used in the diagnosis of fungal infections, Whiff test for bacterial vaginosis, treatment of male genital warts, and the treatment of molluscum contagiosum in children [14-17]. It acts by its keratolytic effects that lead to the destruction of virus-infected cells causing resolution of warts. Potassium hydroxide is less irritating, less painful, less scar forming, and can be safely used in children too. Rarely, side effects such as itching, erythema, and dyspigmentation may be seen. KOH holds better promise for the

61	treatment of warts according to a few studies [18]. Hence, it was felt worthwhile exploring this
62	agent for the treatment of plane warts.
63	The aim of this study was to compare the efficacy and safety of topical 10% KOH with 50%
64	TCA in the treatment of plane warts.
CF	
65	
66	Materials and Methods
67	A randomized, controlled trial was conducted at the Department of Dermatology, Ahvaz Imam
68	Hospital, Southwest Iran, during August 2017 to February 2018. A total of 64 patients with age
69	more than 4 years and plane warts ranging from 3 to 30 in number were included in the study.
70	Pregnant and nursing women, patients with hypersensitivity to KOH or TCA, patients currently
71	using any treatment for warts within the last 1 month, patients with comorbid conditions such as
72	diabetes mellitus or immunosuppression were excluded from the study. They were randomized
73	into two groups of thirty-two and matched with respect to the age and sex. A four random
74	permutation method was chosen to select the patients for both groups. Informed consent form
75	was taken and ethical clearance obtained from the University Ethical Committee
76	(IR.AJUMS.REC.1396.703). The diagnosis of plane warts was made clinically with special
77	attention to the morphology of lesions and loss of skin markings over the lesions. Location, size,
78	and number of warts were recorded. Group A received topical 10% KOH solution and group B
79	received topical 50% TCA solution once weekly by the physician. In both groups, a cotton-
80	tipped toothpick dipped in the solution was applied once to the wart under Vaseline cover of
81	surrounding skin, keeping it perpendicular to the skin surface. The patients were observed for 15
82	min for any side effects. The therapy was continued until the completion of 12 weeks or till all
83	the lesions cleared, whichever was earlier. Both the groups were examined at the end of 4 weeks,
84	8 weeks, and 12 weeks to evaluate the response to treatment and for any side effects. Clinical
85	resolution of the warts was determined by objective responses. Patients, physician and those who
86	measured the results did not know how to place patients in the groups, as well as the drugs were
87	prepared similarly in terms of appearance (packaging, color and odor).
88	Based on physician's perception of overall percentage of resolution of warts, patients were

classified as complete responders: Complete disappearance (100%) of all the warts both in size

and number, partial responders who were in turn classified as moderate responders: More than
 50% (51-99.9%) reduction in number of warts, mild responders: <50% (1-50%) reduction in
 number of the warts and non responders: No reduction in the number.
 Data analysis was performed using SPSS version 24. Mean and standard deviation for
 quantitative variables and absolute and relative frequencies for qualitative variables were
 determined. The therapeutic efficacy level in the two groups was compared with the chi-square
 test and the significance level was 0.05.

97

Results

A total of 64 patients (32 in each group) were finally assessed at 12 weeks. Twenty-nine (45.3%) patients were males and 35 (54.7%) were females. Age of the patients ranged from 4 years to 51 years, duration of warts from a week to 5 years, number of warts varied from 3 to 30, and size of smallest wart ranged between 1 and 2 mm. The wart location and demographic variables of each group have been collected in Table 1. Both the groups were comparable with respect to different independent variables including sex, age, number, size, and duration of lesions (P > 0.05). No patient had any comorbidities or any state of immunosuppression.

Study results at 12 weeks showed that in KOH group, 24 patients (75.0%) had complete 105 response, 5 patients (15.6%) moderate response, 2 patients (6.3%) mild response, and 1 patient 106 (3.1%) had no response. In TCA group B, 28 patients (87.5%) showed complete response, 2 107 patients (6.3%) moderate response, 2 patients (6.3%) mild response. Statistically no significant 108 difference was found between the therapeutic response to 10% KOH and 50% TCA (P=0.41) 109 [Table 2]. However, it was noticed that the percentage of patients showing complete clearance 110 (100% response) was more in TCA group which was 87.5% as compared to 75% in KOH group 111 but no statistical significance was found. On analysis, the average percentage reduction in 112 number of warts in two groups showed no statistically significant results (P = 0.41)[Figures1,2]. 113

114 On comparison of the response in the two groups based on the site of warts, size of warts, sex of 115 patients, age of patients, and duration of disease no statistical difference was observed (P >

116

4

0.05).

127

Burning sensation occurred in 25 patients in KOH group immediately after consumption for a 117 transient period of less than one minute and in 32 patients in TCA group for a transient time of 1-118 119 2 minutes. Erythema was seen in all patients in TCA group during the procedure which disappeared within 10-15 min. Crust was also seen in 10 patients in KOH group and in all 120 121 patients in TCA group at the place of consumption. Dyspigmentation was seen in 14 patients in KOH group (hypo-hyperpigmention) and in all patients in TCA group which was completely 122 resolved during follow-up, except for 2 cases of hyperpigmentation, both of which were children 123 and hyperpigmentation was still evident one month after discontinuation of treatment, but had 124 color reduction. On follow-up of the patients with complete response after 2 months, two patients 125 had recurrence of warts in TCA group. 126

Discussion

A multitude of therapies is available for the treatment of common warts with varying degrees of 128 success ranging from the age-old destructive treatment to cryotherapy and the newly emerging 129 therapies such as pulsed dye laser, intralesional immunotherapy, and autoinoculation therapy 130 [9,11,19]. However, studies on plane warts are scarce. There are insufficient data available to 131 show the efficacy and strength of recommendation for topical destructive or caustic agents which 132 are safer, inexpensive, and easy to use in case of plane warts. This study compared the efficacy 133 of such two well-known agents, 10% KOH, and 50% TCA in the treatment of plane warts. It was 134 noticed that the average percentage reduction in wart number at the end of 12th week. show no 135 difference. 136

In one of the most recent studies, by examining the solution of KOH 5% and the tretinoin lotion
0.1% in 72 patients with plane warts for 6 weeks, Yaghoobi et al. (2016) showed that 59.8% in
the KOH group and 64.1% in the tretinoin group decreased lesions. Side effects in the KOH
group were slightly higher than the tretinoin group [20]. In our present study, the efficacy of both
drugs was higher than that of Yaghoobi *et al.*, while there was no significant difference between
the two groups like their study.

Al-Hamdi and Al-Rahmani[18] compared the effects of 5% and 10% KOH on plane warts with
once daily application for 4 weeks. Patients under treatment with 5% KOH showed 80.3%

145 complete response in comparison with 82.1% of 10% KOH group. Nearly 14.7% showed partial response and 3.15% showed no response in 10% KOH group. The difference in the cure rate for 146 147 patients showing complete disappearance was not significant at the end of therapy. However, 5% KOH solution showed a slower action in comparison with 10% KOH solution. In addition, the 148 149 recurrence rates of warts among patients showing complete response were 5.8% in 5% KOH group versus 5.1% in 10% KOH group. all the warts in the study by Al-Hamdi and Al-Rahmani 150 151 were located on the face. This study has closer efficacy to the current study, and it can express more general findings in the effective use of these drugs. 152

153 In another single-blinded clinical trial by Pezeshkpoor *et al.*,[12] 62 patients with common warts were randomly divided into two groups and were applied 80% TCA or 35% TCA once per 154 week until complete clearance of the lesions for a maximum duration of 6 weeks. Results 155 showed good response rate 46.7% in group 80% and good response rate 12% in group 35%, 156 157 which was significant in improvement between the two treatment groups. Improvement was greater with a higher concentration of TCA solution (80%). The results showed that 35% TCA 158 had a lower clearance rate seen at the end of 6 weeks (12%) which is almost similar to our study 159 (11.11%) at the end of 12 weeks. It can be interpreted that more time is probably needed for 160 TCA to show complete response or higher concentration (>35%) can be tried. The present study 161 showed more efficacies compared to the study of Pezeshkpoor and examined the wider variables 162

Review of literature shows that TCA in higher concentration (60-80%) has equal cure rates in
 genital warts compared to cryotherapy [11]. The British Association of Dermatologists
 guidelines suggest 50-80% TCA weekly application for 8 weeks for treating hand warts [21].

A study by Taner *et al.* (2007) treated 51 women with genital warts with TCA 85%, showed a
good response to TCA with high efficacy and low morbidity [22]. Although the type of warts
was different in their study and, the effective use of the referred drug was mentioned with a
common goal, such as the present study.

In another study by Jayaprasad *et al.* (2016) by examining 60 patients with plane warts treated by
30% TCA or 10% KOH, the therapeutic efficacy of KOH was better at the end of 4 and 8 weeks
but at the end of 12 weeks, there was no difference between two groups [23]. The main
difference between their study and the present study was the difference in the efficacy of the

174	drugs at the end of 4 and 8 weeks. The follow-up of patients was also more in that study that
175	could also examine differences of both groups in the long term, whereas this is not the case in
176	this study.

Also, the use of non-pharmacological methods along with KOH has also shown that this drug is
effective and competitive and comparable with other methods for the improvement of patients,
including Asadi *et al.* in 2016 in Iran divided 70 patients with warts into two groups of CO2 and
KOH laser recipients, which the results showed that88.9% in both groups were fully cured and
the efficacy of the two methods was statistically similar [24].

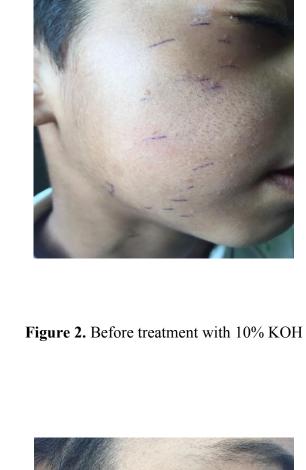

182	Similarly, in the study of Cengiz <i>et al.</i> , patients with plane warts were divided into three groups:
183	cryotherapy, TCA 10% and TCA 25% that the response to treatment was similar in three groups,
184	and finally 10% TCA was introduced as a more convenient and safe method [25].
185	Finally, in the study of Layegh et al. 60 women with genital warts received 80% TCA or
186	cryotherapy. the response to treatment in the TCA group was 96.5% and in the cryotherapy
187	group was 93.1%. Relatively, TCA had a faster efficacy in the treatment process [26].
188	Overall findings indicate that KOH and TCA could be used as safe and effective choices, not
189	only in comparison with other drugs, but also in comparison with other therapeutic methods.
190	Conclusion
191	This study showed that use of 10% KOH solution and 50% trichloroacetic solution in patients
192	with plane warts could effectively improved plane warts. Both the agents are less expensive, easy
193	to apply, and well suited for the self-treatment of plane warts by the patients. Hyperpigmentation
194	seen with 50% TCA may make it less promising in the treatment of plane warts over the face in
195	young females. Also, 10% KOH can be considered as an effective, safe, cosmetically acceptable,
196	and first line therapy for plane warts in immune competent individuals.
