5 Cold plasma is an electrically energized matter composed of highly reactive species which

6 includes molecules of charged and gas particles in the form of positive ions, and negative

7 ions, photons electrons, and free radicals at room temperature. It is an emerging technology

in non-thermal food preservation in the application of sterilization. An increase in the

plasma based treatment for food is employed to inactivate the food borne pathogens clearly

10 seen in the recent years. The present study reviews the action of plasma agents on the

microbial elasses population, surface decontamination of the raw produce in the food

processing and novel technologies with future view in applications of food.

13 **Key words:** Cold plasma, Food, preservation, sterilization.

14 Introduction

15 Matter on earth exists mostly in three distinct phases (gas, liquid and solid) but when

universe is considered as fourth state of matter which abundantly exists. So, Plasma is

17 hence referred to as the fourth state of matter, next to solids, liquids and gases. The term

18 'Plasma' was first employed by Irving Langmuir in 1928 to define this fourth state of matter

19 which is as partially or wholly ionized state of gas and discovered plasma oscillations in

20 ionized gas. The phase Matter changes from solid to liquid and further to gas occurs as we

21 increase the energy input likewise increasing the energy input beyond a certain level in gas

state causes ionization of molecules which yields the to plasma state. d Agostino et al.

23 (year) reported that plasma can be obtained either in low temperature, non-equilibrium glow

24 discharge or high temperature, equilibrium thermal plasma.

25 From the properties of plasma, it is used in various fields such as textile, -electronics, life

sciences, packaging etc. Roth et al. (year). Application of the plasma technology as a

27 surface cleaning tool has been commercially adopted for the removal of disinfection

al., year). In the biomedical sector, plasma technology is sused for cold sterilization of

89

90

active particles recombine with each other, the energy is released as visible and UV light in 61 the process of recombination (Lieberman & and Lichtenberg 2005; Niemira, 2012). Of 62 more interest to food processors, the active particles in the plasma can react with the food 63 substrate, releasing the stored energy into the bacteria or viruses to be targeted. How much 64 energy a plasma has to impart will depend on its chemical composition, density, and 65 66 applied temperature. Plasma Science (Plasma- Definition, Physics and Chemistry) 67 In 1922, the American scientist Irving Langmuir proposed that the electrons, ions and 68 Formatted: Indent: First line: 0" neutrals in an ionized gas could be considered as corpuscular material entrained in some 69 kind of fluid medium and termed this entraining medium "plasma", similar to the plasma, 70 introduced by the Czech physiologist Jan Evangelista Purkinje to denote the clear fluid 71 which remains after removal of all the corpuscular material in blood. However, it emerged 72 that there was no "fluid medium" entraining the electrons, ions, and neutrals in an ionized 73 gas (Bellan 2015), nevertheless the name prevailed. 74 Comment [JTK12]: Chai and Bellan, 2015 not Bellan, 2015 The term "plasma" refers to a partially or wholly ionized gas composed essentially of 75 photons, ions and free electrons as well as atoms in their fundamental or excited states 76 possessing a net neutral charge. The plasma possesses a net neutral charge because the 77 number of positive charge carriers is equal to the number of negative ones (Kudra and 78 Mujumdar 2009). Electrons and photons are usually designated as "light" species in contrast 79 to the rest of the constituents designated as "heavy" species. Due to its unique properties 80 plasma is often referred to as the fourth state of matter according to a scheme expressing an 81 increase in the energy level from solid to liquid to gas and ultimately to plasma. 82 **Definition of Technology** 83 Thermal plasma, operating at many hundreds or thousands of degrees above ambient, would-84 Formatted: Indent: First line: 0" 85 be immediately detrimental to the quality of food products. Non thermal plasma is therefore the focus. For the sake of clarity, however, a distinction must be made between what non 86 thermal means to a plasma physicist and what the same term means to a food processor. To 87

the a physicist, non-thermal means that the plasma has a distinctly non uniform distribution

of energy —(a non-equilibrium) among the constituent particles. Electrons are likely to

transfer energy via collisions with heavier particles, exciting the larger particle in-to a state

of reactivity (Fridman et al. 2005, Niemira & Gutsol, 2010). To a food processor, nonthermal means that the mode of action of the antimicrobial process does not rely on thermal heat-kill for inactivation of associated pathogens. As a practical matter, non-thermal processes are generally regarded as those that cause little or no thermal damage to the food product being treated. There are three primary mechanisms by which cold plasma inactivates microbes (Moisan *et al.*, 2002).

Formatted: Font: 11.5 pt, Highlight

Comment [JTK14]: Please delete to avoid tautology.

Formatted: Font: 11.5 pt, Italic

- The first is the chemical interaction of radicals, reactive species, or charged particles with cell membranes.
- The second is by damage to membranes and internal cellular components by UV radiation
- Finally, DNA strands may be broken by UV generated during recombination of the plasma species.

While on a given commodity, one mode of action may be more significant than another. However, the greatest sanitizing efficacy results is from plasma with multiple antimicrobial mechanisms (Moisan *et al.*, 2002; Laroussi 2003). As a food processing technology, cold plasma is new enough that the terminology is still evolving. The terms cold plasma (Noriega et al. 2011), cool plasma (Tran *et al.*, 2008), atmospheric pressure plasma (Chirokovetal.2005), cold atmospheric gas plasma (Moisanetal.2001), and other comparable terms have been used in recent publications. In other cases, the plasma is described by the generative technology, e.g., dielectric barrier discharge (Fridman et al. 2006), plasma jet (Lu et al.2009), uniform glow discharge plasma (Gadrietal.2000), gliding arc discharge (Burlica et al. 2010), etc.

Types of Plasma

Two classes of plasma, namely thermal and Non-thermal plasma (NTP) can be distinguished on the basis of conditions in which they are generated. This classification of plasma is based on the relative energetic levels of electrons and heavy species of the plasma. NTP (near ambient temperatures of 30-60°C) is obtained at atmospheric or reduced pressures (vacuum) and requires less power (citation?). NTPs are characterized by an electron temperature much above that of the gas (macroscopic temperature) and consequently do not present a local thermodynamic equilibrium. NTP is also generated by an electric discharge in- gas at lower pressure or using microwaves.

Typical illustrations for plasma generation at atmospheric pressure include the corona discharge, Dielectric Barrier Discharges (DBD), Radio-frequency Plasmas (RFP) and the gliding arc discharge. To the contrary, thermal plasmas are generated from higher pressures and require high power. Thermal equilibrium may exist in between the electrons and the heavy species. Plasma generation at atmospheric pressure is of interest, both technically and industrially for the food industries because this does not require extreme conditions.

A thermal plasma is characterized by the existence of a thermodynamic equilibrium between the electrons, ions and neutral particles. The temperatures of a thermal plasma at atmospheric pressure generally are above 6000 K. This corresponds to a mean kinetic energy of less than 1 ev. while

A non-thermal plasma has significantly different electron and gas temperatures. For example, the electron temperature may be several 10,000 K, which corresponds to a mean kinetic energy of more than 1 eV, whereas the gas temperature can be close to ambient. In spite of their low temperature, such plasmas can trigger chemical reactions and excitation states via electron impact (citation needed). In Contrast thermal plasma, non-thermal plasma can also be applied directly to thermally sensitive surfaces.

Formatted: Indent: First line: 0", Space After: 9.4 pt

Comment [JTK20]: This statement is not needful here. The mechanism explains their sensitivity.

Plasma Sources

Usually, plasma treatments was were carried out under vacuum conditions, but researchers have developed atmospheric pressure plasma system; with advantages of resulting reduced cost, increased treatment speed, and industrial applicability (Yoon and Ryu 2007; Yun et al., 2010). The ability to generate non-thermal plasma discharges at atmospheric pressure makes the decontamination process easier and less expensive (Kim et al., 2011). Nevertheless Nevertheless, recently, most of the cold plasma devices available commercially was developed for research to aim at biomedical applications. Therefore, for food applications, these devices may need to be customized or tailor made. The barrier glow discharge generated between two parallel electrodes is a widely employed NTP system.

Food may be conveyed through the discharge to achieve microbial decontamination in most of the industrial scale. Another configuration is the plasma pen or jet, in which a stream of gases can be directed at the object to be treated. Biozone, a Scientist has developed the new process for the generation of the cold oxygen plasma (COP) by using air to high- energy

deep UV light with an effective radiation spectrum between 180 nm &and 270 nm. This 152 cold gas plasma, composed of several species of negative and positive ions, free radical 153 154 molecules, electron, UV-photons and ozone (Terrier et al., 2009). Duo-Plasma line is Formatted: Font: 11.5 pt, Italic linearly extended plasma source excited using microwaves of 2.45 GHz at a pressure <1000 155 Pa (Petasch et al., 1997) and several other plasma treatment systems have evolved based on 156 Formatted: Font: 11.5 pt, Italic 157 this principle. The Plasmodul is a microwave sustained low pressure plasma reactor with a modular concept based on the Duo-Plasmaline principle which provides an easy up scaling 158 159 for industrial applications (Schulz et al. year). Formatted: Font: 11.5 pt, Italic 160 This type of microwave excited plasma sources are is well suited for large area plasma treatment (Petasch et al., 1997) and can probably be employed for surface treatment of 161 Comment [JTK24]: Not referenced... Formatted: Font: 11.5 pt, Italic foods or processing surfaces at industrial scale. More recently, Kim et al. (2010) developed 162 Comment [JTK25]: Not referenced a cold plasma jet operating at 20 kHz Alternating Current (AC) under atmospheric pressure. 163 The most changable feature of most plasma systems is the freedom to select a 164 165 gas or gas mixture. Improvements in the existing plasma systems and newer equipment 166 directed for treatment of real food systems are likely to draw attention of researchers and 167 engineers in near future. Recently, a novel approach which shows significant potential for the treatment of various 168 foods has been reported. The approach is based on a dielectric barrier discharge with the 169 food package in contact with high voltage electrodes. Only 40-50 W of power is needed to 170 171 ionize air inside a 4 L re-sealable plastic (LDPE) bag (Klockow and Keener 2009). The high voltage process ionizes any gas within the electric field contained within the package. 172 173 Ionization can generate significant amounts of reactive molecules with little increase in 174 product surface temperature. Particular treatment times for targeted spore or bacterial reductions are dependent on product loading, packaging material, gas composition and 175 package/electrode configuration. The in-package ionization process has been demonstrated 176 177 in a number of common packaging materials including cardboard, glass, LDPE, HDPE, 178 PETE, polystyrene, rubber, tygon, and others. Scale-up of the system has facilitated treatment of air filled packages with an electrode gap of up to 10 cm with rapid processing 179 180 times (Keener et al. 2010). Comment [JTK26]: Not referenced.

Types of Cold Plasma Systems

There is a are rapidly expanding array of technologies used to generate cold plasma. These can operate at atmospheric pressure or at some degree of partial vacuum. The gas being ionized may be as simple as air or nitrogen; or it may be a more exotic mixture containing some proportion of noble gases; such as helium, argon; or neon. The driving energy may be electricity, microwaves; or lasers. This wide array of design elements is an indication of the flexibility of cold plasma systems and the extent to which new forms of cold plasma systems continue to be built and evaluated.

-However, all cold plasma systems intended for use in food processing fall generally into one of three categories. These categories are defined by where the food to be treated is positioned with respect to the cold plasma being generated: at some significant distance from the point of generation, relatively close to the point of generation, or within the plasma generation field itself. Conceptually, these categories are derived from the nature of cold plasma chemistry, with delineations having to do with the half-life and reactivity of charged, active species within the plasma (Niemira &and Gutsol, 2010).

The first category is remote treatment cold plasma systems. The plasma is generated using one of a variety of methods and moved onto the surface to be treated. The plasma may be driven by a flow of the feed gas or (less commonly) manipulated through the use of magnetic fields. This type of system has the advantage of placing the surface to be treated at a physically separate point of generation (Chirokov *et al.*, 2005). This simplifies the design and operation of the device, and increases the flexibility with respect to the shapes and sizes of objects to be treated. However, the most reactive chemical species are also those that have the shortest half-life. During the time of flight, free electrons may recombine with other plasma products, such as heavy ions or atomic species. By the time the quenched plasma reaches the target surface, the composition is secondary chemical species, i.e. lower activity, long-living chemical species resulting from chemical recombination within the plasma (Gadri et al. 2000).

The lower concentration of ions that exist in this afterglow plasma generate UV light and activate chemical species upon reaction with the target, but their concentration is much lower than in active plasma (i.e., plasma supported by electric field) (Fridman & and Kennedy 2004). Thisese Conditioned category is known as direct treatment cold plasma

Formatted: Indent: First line: 0"

Formatted: Font: 11.5 pt, Italic

Comment [JTK27]: Not refrenced.

systems. In this systems, plasma generation instrument supplies active plasma directly to 212 the object to be treated. As with the first category, the plasma is moved via the flow of the 213 214 feed gas or by a comparable means. So the target is relatively close to the site of cold plasma generation & eand exposed to the plasma before active species recombine and are 215 lost. These systems provide higher concentrations of active agents (Laroussi and Lu. 216 217 2005). Systems of this type can operate in pulsed mode, with plasma generated at pulse Comment [JTK28]: Not referenced. frequencies of hundreds or thousands of times per second. 218 219 220 **Cold-Plasma Generators** 221 In this section, several methods that have been used to generate relatively large volumes of 222 Formatted: Indent: First line: 0" 223 non-equilibrium cold plasmas, at or near atmospheric pressure (sometimes referred to as "high" pressure) are presented. This is not a comprehensive list of all existing methods. The 224 225 methods presented here were chosen for two main reasons. 1. They have been used extensively to study the germicidal effects of cold, high 226 pressure plasmas; and 227 228 2. Their potential use in various other industrial plasma processing applications (lighting, surface modification, etching, deposition). 229 Formatted: Indent: Left: 0", Right: 0", Space After: 5.45 pt The Corona Discharge 230 231 Siemens (2005) was the first to suggest the use of a corona discharge to generate ozone in Comment [JTK29]: Not referenced. order to disinfect water supplies. Fig:1: The Glow Discharge at Atmospheric Pressure

One of the early developments of diffuse glow discharge plasma at atmospheric pressure was reported by Donohoe and Wydeven. Donohoe (1979). They used a large gap (cm) pulsed-barrier discharge in a mixture of helium and ethylene to polymerize ethylene. Later, Kanazawa et al. (1979). reported their development of a stable glow discharge at atmospheric pressure by using a dielectric-barrier discharge (DBD) configuration. They claimed that to obtain a diffuse discharge (as opposed to a filamentary discharge, which is traditionally produced by DBDs), helium had to be the major constituent of the gas mixture, and the frequency of the applied voltage had to be in the kilohertz range. Schematic of the DBD based glow discharge at atmospheric pressure. At least one of the two electrodes must be covered by a dielectric material. After the ignition of the discharge, charged particles are collected on the surface of the dielectric.

This <u>charge</u> builtd-up <u>charge</u> creates a voltage drop, which counteracts the applied voltage, and therefore chokes the discharge current. The <u>discharge which</u> subsequently extinguishes. As the applied voltage increases again (at the second half cycle of the applied voltage) the discharge reignites. This process is repeated over and over during each full cycle of the applied voltage. Laroussi (2003), reported the use of the glow discharge at

The Atmospheric-Pressure Plasma Jet

The atmospheric-pressure plasma jet (APPJ) is a capacitively coupled device consisting of two coaxial electrodes between which a gas flows at high rates. The outer electrode is grounded, while the central electrode is excited by RF power at 13.56 MHz. The free electrons are accelerated by the RF field and enter into collisions with the molecules of the background gas. These inelastic collisions produce various reactive species (excited atoms and molecules, free radicals) that exit the nozzle at high velocity. The reactive species can therefore react with a contaminated surface placed in proximity (cm) of the nozzle.

As in the case of the diffuse DBD, the stability of the APPJ plasma (as well as its non-thermal characteristic) depends on using helium as a carrier gas. Herrmann <u>et al.</u> (1999): used the APPJ to inactivate spores of <u>Bacillus globigii</u>, a <u>simulant to Aanthrax</u> (<u>Bacillus anthracis</u>): and <u>Herrmann et al(1999)</u>: reported the reduction of seven orders of magnitude of the original concentration of <u>B. globigii</u> in about 30 s.

The Resistive Barrier Discharge

The concept of the resistive-barrier discharge (RBD) is based on the DBD configuration. However, Instead of a dielectric, a high-resistivity material is used to cover at least one of the electrodes. The high-resistivity layer plays the role of a distributed ballast which limits the discharge current and therefore prevents arcing. The advantage of the RBD over the DBD is the possibility to use de_DC power (or low-frequency ac, 60 Hz) to drive the discharge.

Using helium, large-volume diffuse cold plasma at atmospheric pressure can be generated. Richardson *et al.*, (2000) and Laroussi *et al.*, reported a four orders-of-magnitude reduction in the original concentration of vegetative *B. subtilis* cells in about 10 minutes. They also reported that the RBD-inactivated endospores of *B. subtilis*, but not as effectively as the

Action on Cell Components and Functions

The use of sterilizing properties of plasma was first introduced towards the end of the '60s, patented in 1968 (Menashi, 1968) and first works with plasma made from oxygen were proposed in 1989. Thereafter, considerable research has been performed on the mechanism of microbial inactivation by plasma agents. The plasma agents contribute to the lethal action by interacting with the biological material. Nelson and Berger (1989) have shown that O2 plasma could be a very efficient biocidal against bacteria.

Plasma treatment can effectively inactivate a wide range of micro-organisms including spores (Kelly-Wintenberg et al. 1999; Feichtinger *et al.*, 2003; Lee *et al.* 2006) and viruses (Terrier *et al.*, 2009). Effect of plasma can be quite selective, meaning tuneable between damage to pathogenic organisms without damage to the host, or activation of different pathways in different organisms (Dobrynin *et al.*, 2009).

Low-pressure oxygen plasma has been shown to degrade lipids, proteins and DNA of cells (Mogul *et al.*, 2003). The reactive species in plasma have been widely associated to the direct oxidative effects on the outer surface of microbial cells. As an example, commonly

Comment [JTK39]: Not referenced.

Formatted: Font: 11.5 pt, Italic

used oxygen and nitrogen gas plasma are excellent sources of reactive oxygen-based and 324 nitrogen-based species, such as O•, O2, O3, OH•, NO•, NO2 etc. Atomic oxygen is 325 Formatted: Font: 11.5 pt, Subscript Formatted: Font: 11.5 pt, Subscript 326 potentially a very effective sterilizing agent, with a chemical rate constant for oxidation at Formatted: Font: 11.5 pt, Subscript room temperature of about 106 times that of molecular oxygen (Critzer et al., 2007). 327 Formatted: Font: 11.5 pt, Italic These act on the unsaturated fatty acids of the lipid bilayer of the cell membrane, thereby 328 impeding the transport of bio-molecules across it. The double bonds of unsaturated lipids 329 are particularly vulnerable to ozone attack (Guzel-Seydim et al., 2004). Membrane lipids 330 Formatted: Font: 11.5 pt. Italic 331 are assumed to be more significantly affected by the reactive oxygen species (ROS) due to 332 their location along the surface of bacterial cell, which allows them to be bombarded by these strong oxidizing agents (Montie et al., 2002). The proteins cells and the spores are 333 Formatted: Font: 11.5 pt, Italic equally vulnerable to the action of these species, causing denaturation and cell leakage. 334 Oxidation of amino acids and nucleic acids may also cause changes that result in microbial 335 336 death or injury (Critzer et al., 2007). Formatted: Font: 11.5 pt, Italic Micro-organisms in cold plasma are exposed to an intense bombardment by radicals, most 337 likely provoking surface lesions that the living cell cannot repair sufficiently faster. This 338 may partially explain the observations where in cells are in many cases destroyed very 339 quickly. This process is termed "etching" (Pelletier, 1992). The cell wall rupture has been 340 additionally attributed by Laroussi et al., (2003) and Mendis et al., (2002) to electrostatic 341 Comment [JTK40]: Adjust the citations. Mendis et al., 2000 not 2002. 2000 should forces due to accumulation of charges at the outer surface of cell membranes. The 342 come before 2003 please. 343 morphological changes in E. coli cells treated with atmospheric plasma at 75W for 2 mins Formatted: Font: 11.5 pt, Italic as observed under an electron microscope by (Hong et al. (2009), clearly revealed that the 344 Formatted: Font: 11.5 pt, Highlight Formatted: Font: 11.5 pt, Italic, Highlight 345 treated cells had severe cytoplasmic deformations and leakage of bacterial chromosome. Formatted: Font: 11.5 pt, Highlight 346 These observations demonstrate the loss of viability of bacterial cells after plasma treatment. An analogy between plasma and pulsed electric field has also been drawn to 347 explain the action of plasma on the membranes (Pothakamury et al., 1995; Spilimbergo et 348 Comment [JTK41]: Not referenced 349 al., 2003). It is well established that electroporation of membranes is induced by pulsed Formatted: Font: 11.5 pt, Italic Formatted: Font: 11.5 pt, Italic 350 electric fields and it appears that plasma acts on similar lines inducing perforations in the membranes of micro-organisms (Sale and Hamilton 1967; Pothakamury et al. 1995; 351 Comment [JTK42]: Not referenced Wouters and Smelt, 1997). In addition to generating pores, humid air plasma additionally 352

provokes a marked acidification of the medium (Moreau et al. 2005; Moreau et al. 2007).

355 356 357 Role of UV photons and charged particles in ...? The production of UV photons of different wavelengths has been proposed to be involved. 358 Formatted: Indent: First line: 0" in dimerizing the thymine bases of DNA including that of spores (Munakata et al. 1991). 359 Comment [JTK44]: Not referenced 360 The role of UV photons in bacterial death when they are submitted to a plasma treatment was reviewed in detail by (Boudam et al., 2006). More recently, by exclusion of -the 361 Formatted: Font: 11.5 pt, Italic reactive particles and spectral fractions of UV radiation from access to the spores Roth et 362 al., (2010) revealed that UV-C radiation is the most effective inactivation agent in the 363 364 plasma. Ultraviolet (UV) photons play a less important role in atmospheric pressure glow discharge 365 Formatted: Space After: 0.05 pt (APGD) because they are easily absorbed by gas atoms and molecules at atmospheric 366 367 pressure (Vleugels *et al.*, 2005). Formatted: Font: 11.5 pt, Italic The role of the charged particles in the bacterial inactivation process was recently 368 Formatted: Indent: First line: 0" 369 investigated by Lu et al. (2009). Their work revealed that the charged particles play a minor Comment [JTK45]: ...2009 0r 2011. Please adjust citation 370 role in the inactivation process when He/N₂ (3%) is used as working gas than when He/O₂ Formatted: Font: 11.5 pt, Subscript (3%) is used. Also, they concluded that heat and UV play no or minor roles in the 371 Formatted: Font: 11.5 pt, Subscript 372 inactivation process. Similar results were earlier obtained by (Perni et al., 2007) who Formatted: Font: 11.5 pt, Italic interplayed bacterial inactivation kinetics with optical emission spectroscopy, and identified 373 374 oxygen atoms as major contributor in plasma inactivation with minor contributions from 375 UV photons, OH radicals, singlet oxygen metastables and nitric oxide. Thus, a contradiction 376 over the role of UV photons in plasma exists and future studies must be directed to get a clear picture. 377 378 **Effect of process parameters** 379 The concentrations in which the plasma agents occur in plasma depend greatly on the Formatted: Indent: First line: 0" 380 device set-up (reactor geometry), operating conditions (gas pressure, type, flow, frequency 381 and power of plasma excitation) and gas composition which affect their efficacy in a process when employed. To cite an example, the destructive efficiency of various gas 382 plasma sources and temperatures on Bacillus spp. spores were compared by (Hury et al., 383 Formatted: Font: 11.5 pt, Italic 384 1998). This group demonstrated that oxygen-based plasma is more efficient than pure argonplasma.

Formatted: Indent: Left: 0", First line: 0"

Another deciding criterion is whether the substrate to be sterilized is in direct contact with 387 the plasma (Pdirect Eexposure) or located remote from it (Rremote Eexposure) (Moisan et 388

Formatted: Indent: First line: 0"

al., 2001; Laroussi 2005; Boudam et al., 2006). If exposed remotely, the quantum of heat

Formatted: Font: 11.5 pt, Italic

transmitted to a sample is reduced, the charged particles do not play a role since they

Formatted: Font: 11.5 pt, Italic

recombine before reaching the sample, and many of the short-lived neutral reactive species also do not reach the sample.

-Since, the components of the plasma are reactive and self-quenching, with a relatively short half-life, decreased time of flight would be expected to be one of the major factors in antimicrobial efficacy in this case (Niemira and Sites 2008).

By varying the process parameters involved in plasma generation, a multitude of mechanisms can be actuated which may act individually or synergistically. Nevertheless, the details of interaction of the different plasma agents with the different components of bacterial cells or spores are currently very limited. The interactions which occur between plasma agents and biological materials, ultimately leading to sterilization are still under investigation.

- 1 Cold plasma treatment to the foods is a promising technology in that which beacause it acts
- 2 rapidly, does not leave toxic residuals on processed parts or in the exhaust gas and the
- 3 temperature rise can be kept to an acceptable level. The viability of grains and legumes had
- 4 | shown to be preserved post plasma treatment with air and SF6 gases (Selcuk et al., 2008).
- 5 Moreover, unlike pulse light and gamma radiation, the shadow effect is minimised
- 6 considerably using gas plasma method as reactive species are produced in the whole
- 7 | chamber (Lassen et al., 2003; Goldman and Pruitt 1998). Contact angle (CA) measurements
- 8 for nonthermal oxygen plasma treated lamb's lettuce have shown increased wettability of
- 9 adaxial leaf surfaces after plasma exposure (Grzegorzewski et al. 2010a).
 - Further, in this case a successive degradation of epicuticular waxes and cutin of the plant's
 - epidermis was indicated by means of FTIR (ATR) and scanning electron microscopy
- 12 (SEM). Above all, it can be conveniently operated in either batch or continuous mode. An
- 13 aspect of the future of plasma technology is the possibility of pairing it with other
- decontamination processes such as pulsed-light treatment where synergistic effects may be
- 15 more appreciable.

Formatted: Indent: First line: 0"

Comment [JTK49]: Not referenced.

Comment [JTK50]: Not referenced. When referenced, please, 1998 comes before 2003 or you can delete Goldman and Pruitt since they concluded on the same matter on effect and mechanism of Gamma radiation.

Comment [JTK51]: Not referenced. Please add to the list of reference.

Studies on effect of nonthermal plasma on food components are scarce in literature. Based 16 17 on the experiments using low-pressure oxygen plasma it have been observed that -time and structure-dependent degradation can be seen for different selected model flavonoids 18 adsorbed on solid surfaces, which was attributed to plasmaimmanent reactive species such 19 as O (3P), O2 ($1\Delta g$ and $1\Sigma g+$), O3, or OH radicals (Grzegorzewski et al. 2010b). It has been 20 Comment [JTK52]: Not referenced. 21 observed in lamb's lettuce that pure compounds show a time-dependent degradation Formatted: Font: 11.5 pt, Highlight (flavonoids) or remain unchanged (phenolic acids) after exposure to oxygen plasma 22 23 (Grzegorzewski et al. 2010a). Formatted: Font: 11.5 pt, Highlight Also, for the same model plant based food, a significant increase of protocatechuic acid, 24 luteolin, and disometin has been recorded after 120 s treatment time, independent of the 25 applied plasma driving voltage. The effect of the UV and radical species of plasma on the 26 lipids and other sensitive constituents of the foods such as vitamins C and E (which are 27 28 naturally occurring in most fruits and vegetables and many foods) still remains ambiguous. 29 Suitability of plasma technology for treatment of high fat/ lipid containing and other 30 sensitive foods (where chemical changes may be induced) is doubted. 31 Products that have high lipid content would likely be affected by oxidation, resulting in formation of hydroxyl acids, keto acids, short-chain fatty acids and aldehydes etc. that cause 32 off-flavours and odours. For these reasons meat products may not be ideal substrates for 33 treatment with plasma (Critzer et al., 2007). For a full evaluation, additional issues 34 Formatted: Font: 11.5 pt, Italic 35 concerning food quality must be considered and these include changes in nutrient content colour and textural qualities, toxic residues and other chemical changes (Vleugels et al., 36 Formatted: Font: 11.5 pt, Italic 2005). Research efforts must be undertaken to evaluate the projected cost of the treatment 37 for large quantities of food commodities and also the safety of gases used before direct 38 plasma techniques will become common in the food industry (Basaran et al. 2008). 39 Therefore, cold plasma technology is an emerging disinfection method that offers an 40 41 exciting complementary or alternative, novel non thermal approach for reducing the 42 microbial populations on the raw or fresh produce surface and packaging materials. There may be several other applications in relation to food systems, which still remain unexplored. 43 Various reactive species of plasma interact with the biological cells to cause permanent 44 changes in them at cellular level and morphology, leading to inactivation. 45

Although cold plasma technology is not yet used commercially on a large scale, the 46 equipment should be readily scalable. Systems for large scale cold plasma treatment of food 47 and related products using various energy sources and methods (like a multiplicity of 48 microwave magnetrons) are already under development. This technology is increasingly 49 Comment [JTK53]: Citation please. finding acceptance among food processors for the surface sterilization and combating 50 51 biofilm formation. The effect of cold plasma on the sensitive constituents of foods, mainly lipids, vitamins etc. have still some issues that need to be addressed and once this is 52 53 achieved the technology will find wider applications and adaptation in food industries. Further research needs and conclusions 54 Comment [JTK54]: I suggest you can change this title to Conclusion and Recommendation 55 Further development of cold plasma technology will have to be carried out, allowing a Formatted: Indent: First line: 0" better understanding of the complex interactions during applications, such as food surface 56 57 interactions, impact on food composition, optimization of gas composition and other processing parameters according to the treated sample. Also, additional information 58 regarding food quality must be considered with respect to the cold plasma treatment, and 59 changes concerning the nutrient content, toxic residues or textural qualities should be 60 investigated. 61 Cold plasma treatment proved to be a flexible, efficient, chemical-free antimicrobial process 62 63 and it can represent an easy to use sanitizing method for the food industry that does not require special temperature, humidity or pressure conditions. The application of a plasma 64 treatment on different commodities represents a relatively new decontamination approach 65 of this technology and more research studies are needed if it is to provide a commercial 66 applicability for the food industry. Comment [JTK55]: Swap the paragraphs. 67
