# The Effects of Mulches on Tomato (*Lycopersicon* esculentum L.) in Respect of Yield Attribute in Ecosystem of Coastal Bengal

## 5 ABSTRACT

Mulching has become an important practice in modern field production. The use of mulches in 6 7 vegetable production is undergoing a radical change away from high input, nonrenewable resources, 8 such as plastic, to the use of high-residue organic mulches from cover crop. The purpose of this 9 present study was to compare the growth and yield of tomato when grown under different organic and inorganic mulches. The experiment was conducted with four treatments in two consecutive years 10 11 (2016-2017 and 2017-2018) at instructional farm of Sasya Shyamala Krishi Vigyan Kendra, 12 Arapanch and different blocks of South 24 Parganas district. Among the treatments, maximum yield 60.3 t/ha and 58.7 t/ha were recorded under poly mulches in the consecutive years. 13

14 Keywords: Mulching, Tomato, Growth, Yield, Coastal Belt

### 15 **1. INTRODUCTION**

Tomato is the second most consumed vegetable in the world after potato [1]. Tomato fruit constitute 16 rich source of essential amino acids, minerals, and vitamins [2]. The fruit is also rich in lycopene 17 which is known to reduce the risk of cancer [3]. About 68% of the global tomatoproduction is 18 consumed fresh while theremaining 32% are processed [4]. Tomato is a regular part of the diet of the 19 20 average Indian household. It is mostly used for fresh vegetable, salad and processing products like 21 puree, ketchup, sauce etc. It is an important crop grown almost throughout the year but generally it 22 cultivated abundantly in coastal Bengal during two consecutive rabi seasons, when the rainfall is 23 scare and soil moisture is exhausted by evapo-transpiration. It was reported that water directly affects the tomato yield, as it contains 94% water [5]. For successful crop production about 285 mm 24 water is required during plant establishment, flowering, fruit setting and fruit development stage [6]. 25 26 But irrigation facilities in all the regions are not available. Sometimes, many of the farmers can't able 27 to provide irrigation due to unavailability of irrigation facilities or even can't afford the expenses of irrigation. Under this situation mulching could be a good substitute means for irrigation to make soil 28 29 moisture available. Mulching has been reported to be increased yield by creating favorable soil temperature and moisture regimes [7]. Mulching is an effective method of manipulating crop growing 30 environment to increase yield and improve product quality by controlling weed growth, ameliorating 31 soil temperature, conserving soil moisture, reducing soil erosion, improving soil structure and 32 33 enhancing organic matter content [8, 9]. The weed control efficiency of different types of mulch in 34 cavenne pepper production ranged from 27% to 97% [10]. Since, the land holdings are very small in 35 this region; therefore, there is a need of conservation farming and sustainable agriculture to improve the environment. There are several organic and inorganic mulches, but due to the property of 36 37 reflectance of plastic mulches, they are used more or much beneficial to minimize the incidence of 38 viral diseases and deter the approach to some species of insect pests. The potential of mulches to 39 improve soil structure, increase organic matter, and establish patterns of nutrient cycling more similar 40 to natural ecosystems has been recognized. Polyethylene mulches have induced large increases in 41 growth and yields for tomato [11]. Use of mulches for crop offers great scope to plant growth by improving water infiltration, retention, and reducing runoff. It reduces and controls soil erosion by 42 providing a cover on the soil surface [12]. Therefore, the study reported in this paper sought out to 43 compare the impact of different types of mulches (organic and inorganic) on the performance of 44 45 tomato production.

### 46 2. MATERIALS AND METHODS

47 The experiment was laid out at the instructional farm of Sasya Shyamala Krishi Vigyan Kendra, 48 Ramkrishna Mission Vivekananda University, Arapanch and also in different villages of Baruipur, 49 Falta, Bhangore-I and Bishnupur-II blocks of South 24 Parganas district during rabi season from 50 2016-2017 to 2017-2018. The main objective of the study was the evaluation of the efficiency of 51 different types of mulches (organic and inorganic) on the performance of tomato (var. Rocky) yield 52 along with respect to C:B ratio. The treatments were considered as four levels of different mulch materials:, viz.,  $T_1$ : Farmers' practice (no mulch),  $T_2$ : Mulching with Jute felt,  $T_3$ : Poly mulch and  $T_4$ : 53 54 Straw mulch. Different irrigation strategy was taken as per different treatments. The experiment 55 was laid out in a randomized block design (RBD) with five replications. Thirty days old tomato var. Rocky were transplanted at the spacing of 60 cm × 40 cm in the month of November. Farm yard 56 57 manure (FYM) enriched with Trichoderma viride at @ 250 kg/ha. After 15 days of transplanting 58 stalking was done to provide better support from lodging and irrigation was done after application of 59 fertilizer. Neem seed karnel extract (NSKE) 10,000 ppm - 3ml/l has been sprayed twice to protect 60 the biotic stress. Other intercultural operations like weeding, irrigation and plant protection 61 measures were taken as deemed needed as per as crops and field conditions.

Data were collected from randomly selected plants for each plot and the recorded data were analyzed statistically by the technique of "Analysis of variance" and significance was tested by variance ratio *i.e.*, value at 5% level of significance [13]. Economic analysis of each and every treatment also worked out.

#### 66 **3. RESULTS AND DISCUSSION**

#### 67 3.1 Number of effective branches per plant

68 From the study it was revealed that the mulching of the soil significantly increased the number of effective branches per tomato plant in comparison to the plants having farmer's practices (without 69 70 any treatment). It can be concluded from the observations of consecutive two years data, the number of branches per plant of tomato under farmer's practices  $(T_1)$  and jute felt mulching techniques  $(T_2)$ 71 72 had not shown any remarkable variations, but straw mulching technique (T<sub>3</sub>) significantly increased 73 the branches/plant as compared to  $T_1$  and  $T_2$ . The maximum number of branches per plant was 74 recorded under poly mulching and need based irrigation ( $T_3$ ). In the year 2017-2018, it was reflected 75 that poly mulching with black polythene resulted maximum number of effective branches per plant 76 (12 per plant) followed by straw mulched plot (10 per plant). Other results of different treatments also 77 depicted in the Table 2. The same result was found in the first year also that the maximum number of 78 branches per plant was obtained in the poly mulched tomato plot (Table 1). So it can be concluded 79 that the poly mulching was provided highest number of branches per plant [14]. Mulching process is effective in reducing evaporation, conserving soil moisture, increase the infiltration rate of rain or 80 irrigation water, modify the hydrothermal regime of soil [15], improve soil physical conditions by 81 enhancing biological activity of soil fauna and thus increased soil fertility [16]. Among different 82 83 mulching treatments, polythene mulching technique was found to increase the crop growth as 84 indicated by effective branches per plant that might be consequence of the reduced leaching of 85 nutrients, weed problems and evaporation of soil water and increased water use efficiency by the 86 plant [17, 18, 19, 20].

112 DUNCAN test.

### 114 **3.2 Number of fruits per plant**

115 The study showed that the mulching techniques significantly increased the fruit per plant as 116 compared to the farmer's practices. From the two year observations (2016-2017 and 2017-2018) the 117 picture was crystal clear that maximum number of fruits per plant was obtained in poly mulching and 118 need based irrigation treatment ( $T_3$ ) followed by  $T_4$ ,  $T_2$  and  $T_1$  (Table 1 and 2). Comparison of 119 different mulches reveled that maximum value was found in poly mulching (black polythene mulch) 120 which was significantly higher than other mulching treatments, whereas minimum number of fruits 121 per plant was observed in control (Flood irrigation without mulching and need based irrigation) that were 52 (Table 1) and 51 (Table 2) fruits per plant in the consecutive years of study. Among 122 123 mulches, black polyethylene treatment produced significantly higher fruit yield and number of fruits per plant than organic mulches and no mulch this might be the result of weed free field, less nutrient 124 125 loss through leaching favorable soil temperature and moisture [21]. Similar findings were also obtained mulched and non-mulched plots [22, 23, 24, 25, 26]. 126

### 127 3.3 Fruit weight

Significant effects were found on weight of mature tomatoes in Rocky cultivars under different 128 129 treatment mulched conditions. Among mulch treatments, it is clear from the data (Table 1 and 2) that 130 black polyethylene mulch significantly increased the weight of the fruits over control. Maximum test fruit weight was in black polythene mulch (784.0 g in the year 2017-2018, Table 2 and 778.5 g in 131 132 2016-2017, Table 1) which was at par with straw mulch (test weight of 10 fruits were 704.0 g and 699.9 g in 2017-2018 and 2016-2017) and found higher than all other treatments, whereas minimum 133 134 was observed in Farmers' practice *i.e.*, T<sub>1</sub> (641.6 g and 629.0 g in back to back experimental 135 seasons). Weight of fruits under mulch conditions was found to be highest and same characters were 136 lowest in control or no mulch treatments [27]. This increase in tomato yield may be due to the better development of roots and vegetative growth, better nutrients uptake in mulched plots, and less 137 normal leaching of nitrogen. Tomato grown under plastic mulches resulted in significant increase in 138 139 vield, earliness and fruit quality [28].

### 140 **3.4 Number of irrigation**

When compared to other mulches plastic mulches are completely impermeable to water; it therefore 141 142 prevents direct evaporation of moisture from the soil and thus limits the water losses and soil erosion 143 over the surface. In this manner it plays a positive role in water conservation. The suppression of 144 evaporation also has a supplementary effect; it prevents the rise of water containing salt, which is 145 important in countries with high salt content water resources. It was reflected in the experiment also. As per depending on the soil status and growing condition of the plant irrigation activities was taken 146 147 in the consideration. It was documented from the overall study of two consecutive years (Table 1 and 148 2) that the less number of irrigations (6 nos. in first year and 5 nos. in second year) was needed in 149 the poly mulch situation  $(T_3)$  in respect to other treatments as per the optimum plant vigour as well as 150 plant health considering the soil status. Whereas maximum number of irrigation was given in farmers' practices  $(T_1)$ . Highest water use efficiency in application of irrigation at developmental stages of 151 152 solanaceous crops [29].

### 153 **3.5 Yield**

154 It can be opined from the overall study that the much higher yield can obtained from mulched plots 155 than non-mulched plots. It can be referred that the mulched environment was responsible for far better yield of tomato. Different level of yield hike was signified by the various type mulch and it was 156 157 also dislocated in the present investigation also. Statistically significant difference was observed in 158 yield plant due to use of different mulching materials. The maximum yield was recorded from  $T_3$ 159 treatment (60.3 t/ha and 58.7t/ha in two consecutive years), while the minimum yield plant was 160 obtained from farmer's practices (non-mulched plot) 38.7 t/ha in 2016-2017 and 36 t/ha in 2017-2018 (Table 1 and 2). Temperature of soil was higher and weed was almost nil under black poly ethylene 161 162 mulch than the other mulch resulting higher yield of tomato. In the year 2017-18 maximum

marketable yield (Table 2) was found in black polythene mulched plot (58.7 t/ha) followed by straw 163 164 mulched plot (51.8 t/ha) whereas the result was slightly differ from the first year study. From the 165 Table 2 it can be inferred that the highest marketable yield 60.3 t/ha found from black plastic mulched 166 plot followed by mulched with jute felt (52.42 t/ha). It can be inferred from the study that yield (t/ha) differed significantly due to use of different mulching. From overall observations of two years it can 167 be concluded that whereas black poly much responsible for higher production of tomato but non-168 mulched resulted minimum production (Table 1 and 2). It might be occurred due to the effect of black 169 170 poly ethylene as such poly ethylene helps to retain higher soil moisture and temperature compared to 171 other mulch materials. The same trend of the result in tomato production using poly ethylene mulch was observed in the present study [30, 31, 32]. 172

#### 173 3.6 Economics

174 The results showed that tomato production can be described as a labour intensive business venture. 175 Among the list of cost items for the tomato production technology, labour alone accounts for more 176 than 70% of the cost of operations. The cost structure of the trails indicates that a potential user of 177 the mulching technology requires additional investment of organic and inorganic mulch. It can be 178 reported that maximum return can be fetched from black poly mulch. From two years proven that the 179 highest net return was recorded in black poly mulch (2016-2017), Rs. 2,11,910 - per ha and Rs 180 1,90,500<sup>4</sup> per ha (2017-2018) followed by jute felt and straw mulch. Cost benefit ratio were recorded the highest (1.96 and 1.86) for poly mulch followed by jute felt and straw mulch than without mulch 181 (1.58 and 1.53) for two consecutive rabi seasons. 182

#### 183 4. CONCLUSION

184 The maximum growth and yield contributing characters were recorded from black polythene mulch. 185 Plastic mulch is more effective in the control of weed infestation. Temperature rise under the plastic mulch did not impair crop growth. From the results of this study, it could be concluded that black 186 polythene mulch showed the general desirable impacts under this region on tomato growth and yield 187 188 attribute performances. The increase in yield of black mulched was probably associated with the conservation of moisture, improved micro-climate both beneath and above the soil surface, light 189 190 reflection and great weed control which reflected also in terms of higher return.
