# EFFICACY OF DIFFERENT ORGANIC MANURES ON GROWTH AND YIELD PERFORMANCE OF ORGANICALLY GROWN TOMATO

# ABSTRACT

The field experiment was conducted in the Horticultural farm of Sher-e-Bangla Agricultural University, Sher-e-Bangla Nagar, Dhaka -1207 during the period from October 2014 to March 2015 to find out the efficacy of different organic manures and different varieties on the growth, yield performance of organically grown tomato. The experiment comprised of two different factors: Factor A. four types of organic manure [M<sub>0</sub>= Control (No organic manures application), M<sub>1</sub> = Cowdung (30 t.ha<sup>-1</sup>), M<sub>2</sub> = Poultry manure (25 t.ha<sup>-1</sup>) and M<sub>3</sub> = Vermicompost (20 t.ha<sup>-1</sup>)] Factor B. three types of variety V<sub>1</sub> = BARI tomato 15, V<sub>2</sub> = BARI tomato 14 and V<sub>3</sub> = BARI tomato 2. The experiment was laid out in Randomized Complete Block Design (RCBD) with three replications. Encouraging responses were monitored in all respects. Among the treatment combination M<sub>2</sub>V<sub>1</sub> (Poultry manure + BARI Tomato 15) showed the highest plant height, maximum number of flower cluster, number of flower per cluster, number of fruits per cluster and number of fruit per plant with improved fruit size. The maximum yield (86.25 t/ha) was recorded from the treatment combination of M<sub>2</sub>V<sub>1</sub> (Poultry manure + BARI Tomato 15), while the treatment combination of M<sub>0</sub>V<sub>3</sub> (Control treatment + BARI Tomato 2) gave the minimum yield (31.25 t/ha). Therefore, BARI Tomato 15 coupled with poultry manure can be the most suitable for enhanced yield and can be considered a noble practice in sustainable agriculture.

# 1. INTRODUCTION

16 17

18 Over the last two decades, organically grown vegetables have generated significant interest among 19 the consumers and scientists due to healthier products and safer characteristics to human health. 20 Consumers demand for organic vegetables has also on the rise. Therefore, sustainability of vegetable 21 production with higher yield is the prime need to meet consumer demand. Furthermore, sustainable 22 vegetable production has been often reported as an environmentally-friendly production system able 23 to produce food with minimal hazardous effect to ecosystems and environment as well as minimal use of off-farm resources [1]. However, the major drawback of organic vegetable production is the lower 24 25 yield compared to conventional agriculture [2, 3]. Therefore, farmers prefer to use commercial 26 synthetic chemical fertilizers for vegetable production. However, extensive use of inorganic fertilizer 27 may lead to environmental pollution including contamination of groundwater, and soil acidification as well as increase de-nitrification resulting in higher emission of nitrous oxide ( $N_2O$ ) to the atmosphere 28 which is responsible for global warming. Therefore, there is prime need to bring new management 29 30 practice to increase nutrient availability, plant uptake and assimilation, reduce disease intensity in 31 order to close the gap between organic and conventional yields [4, 5]. Application of organic manures can be an effective practice to produce tomato in a sustainable production system. Organic manure is 32 33 a source of food for the innumerable number of microorganisms and creatures like earthworm who 34 breaks down these to micronutrients, which are easily absorbed by the plants. Organic manure plays 35 a direct role in plant growth as a source of all necessary macro and micronutrients in available forms during mineralization, improving the physical and physiological properties of soils. Organic manures 36 37 such as cow dung, poultry manure and vermicompost improve the soil structure, aeration, slow 38 release nutrient which support root development leading to higher growth and yield of tomato plants. 39 The macronutrients calcium and micronutrients boron, manganese, molybdenum and iron are 40 important for tomato cultivation. Biologically active soils with adequate organic matter usually supply 41 enough of these nutrients [6]. Tomato (Lycopersicon esculentum L.) is one of the most popular and 42 versatile vegetables in the world which is cultivated in almost all parts of Bangladesh under both field 43 and greenhouse conditions. Tomato fruits are eaten raw or cooked and other dishes like as soups, 44 juice, Jam, Jelly, ketchup, pickles, sauces, conserves, puree, paste, powder and other products. In 45 terms of human health, tomato is a major component in the daily diet and constitutes an important 46 source of minerals, vitamins and antioxidants, like lycopene. Lycopene pigment is a vital anti-oxident 47 that helps to fight against cancerous cell formation as well as other kind of health complications and 48 diseases [7]. Nevertheless, it plays a vital role in providing a substantial quantity of vitamin C and A in 49 human diet [8]. Increasing the production and improving the keeping quality of tomato are of paramount importance, now-a-days, for meeting the internal demand of the consumers'. Hence efforts 50 should be given to identify varieties with high yield potential in organic production system influenced 51 by the application of different organic manures. Considering the above perspective, the present study 52 53 was undertaken to identify the suitable tomato variety and the efficacy of different organic manures 54 which can promote growth, increase yield of tomato in a sustainable and environment friendly way.

55 56

# 2. MATERIAL AND METHODS

57 58

## 59 2.1 Experimental Site

60 The experiment was conducted at the Horticultural farm of Sher-e-Bangla Agricultural University, 61 Dhaka, Bangladesh from October 2015 to February 2016. The location of the experimental site was 62 23º74'N latitude and 90º35'E longitude and at an elevation of 8.2 m from sea level. The climate of 63 experimental site was under the subtropical climate, characterized by three distinct seasons, the winter season from October to February and the pre-monsoon or hot season from March to April and 64 65 the monsoon period from May to October .The soil of the experimental area belongs to the Modhupur 66 Tract (AEZ No 28). It had shallow red brown terrace soil. The selected plot was medium high land and 67 the soil series was Tejgaon. The physicochemical properties of the soil in the experimental site are as 68 followss

Fextural class	Silty clay loam to clay loam
Bulk density ( g cm⁻³)	<b>1.33</b>

# 69

### 70 2.2 Planting Material

71 Three varieties of tomato were used in this experiment viz,  $V_1$  = BARI tomato 15,  $V_2$  = BARI tomato 14 72 and  $V_3$  = BARI tomato 2.Tomato seeds were collected from Vegetable division, Horticulture Research 73 Centre (HRC), Bangladesh Agricultural Research Institute (BARI), Gazipur, Bangladesh.

## 74 2.3 Organic Materials

75 Four types of organic manure coded as M<sub>0</sub> = Control (No organic manure), M<sub>1</sub> = Cow dung (30 t.ha<sup>-1</sup>),

- 76 M<sub>2</sub> = Poultry manure (25 t.ha<sup>-1</sup>), M<sub>3</sub> = Vermicompost (20 t.ha<sup>-1</sup>). Nutrient composition of different 77 organic manures applied in the experiment is as follows-
- 78

Manure	<mark>N (%)</mark>	<mark>P (%)</mark>	<mark>K (%)</mark>
Cowdung (decomposed)	<mark>1.0±0.1</mark>	<mark>0.3±0.03</mark>	<mark>0.46±0.05</mark>
Poultry manure	1.25±0.13	0.70±0.07	<mark>0.95±0.10</mark>
Vermicompost	<mark>0.75±0.07</mark>	<mark>0.6±0.06</mark>	<mark>1.0±0.1</mark>

### 79 2.4 Experimental Design and Treatments

80 The experiment was laid out in Randomized Complete Block Design with three replications. There 81 were altogether 12 (4 x 3) treatments combination used in each block were as follows;  $M_0V_1$ ,  $M_1V_2$ . 82  $M_2V_3$ ,  $M_0V_2$ ,  $M_1V_3$ ,  $M_3V_1$ ,  $M_0V_3$ ,  $M_2V_1$ ,  $M_3V_2$ ,  $M_1V_1$ ,  $M_2V_2$ ,  $M_3V_3$ . The experimental plot was first divided into three blocks. Each block consisted of 12 plots. Thus, the total numbers of plot were 36. 83 84 Different combinations of treatments were assigned to each plot as per design of the experiment. The 85 size of a unit plot was 2.4 m × 2.4 m. A distance of 0.5 m between the plots and 1.0 m between the 86 blocks were kept.

87

### 88 2.5 Growth Condition of Tomato and application of Manures

89 The experimental land area was prepared by several ploughing and cross ploughing with a power 90 tiller followed by laddering to bring about a good tilth. The land was leveled, corners were shaped and 91 the clods were broken into pieces. The weeds, crop residues and stables were removed from the 92 field. Total organic manures were applied according to their treatment and finally leveled. Thirty days-93 old healthy seedlings were transplanted at the spacing of 60 cm × 40 cm in the experimental plots. 94 Thus the 24 plants were accommodated in each unit plot. 

### 95 2.6 Data Collection and Analysis

96 Five plants were randomly selected from each unit plot for the collection of data. The plants in the 97 outer rows and the extreme end of the middle rows were excluded from the random selection to avoid 98 the border effect. The height of the plants was measured from the ground level to the tip of the 99 highest leaves. The data obtained for different parameters were statistically analyzed to find out the 100 significant difference of variety and different manure application on yield and yield contributing 101 characters of tomato. The mean values of all the characters were calculated and analysis of variance 102 was performed by the 'F' (variance ratio) test. The significance of the difference among the treatment 103 combinations means was estimated by the Duncan's Multiple Range Test (DMRT) at 5% level of 104 probability.

105

## 106 3. RESULTS AND DISCUSSION

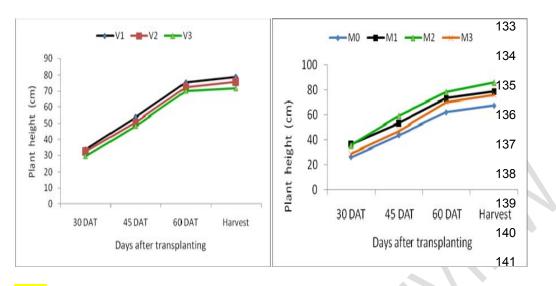

107

#### 108 3.1 Plant height (cm)

Application of organic manures exhibited a significant influence on the height of tomato plants at 30, 109 110 45, and 60 days after transplanting (DAT) and at final harvest (Figure 1). At 30 DAT, the tallest plant (35.68 cm) was found in the application of poultry manure (M<sub>2</sub>) and the shortest plant (26.33 cm) was 111 recorded from control treatment (M<sub>0</sub>). At 45 DAT, the plant height (59.32 cm) was recorded from M<sub>2</sub>, 112 113 while the lowest (43.88 cm) was recorded from  $M_0$ . At 60 DAT, the longest plant (77.35 cm) was 114 recorded from M<sub>2</sub> and the shortest plant (62.08 cm) was recorded from M<sub>0</sub>. At final harvest, plant 115 height ranged from 67.44cm to 83.90 cm. The highest plant (83.90cm) was recorded from M<sub>2</sub>, while 116 the lowest (67.44 cm) was recorded from M<sub>0</sub>. Poultry manure is rich in its nitrogen and nutrient 117 content. This favorable condition creates better nutrient absorption and favors for vegetative growth. 118 Consequently longest plant was found by application of poultry manure. This is an agreement with the 119 findings of [6].

120

121 Different varieties showed significant influence on plant height of tomato plants at different DAT and 122 final harvest (Figure 1). At 30 DAT, the tallest plant (33.71 cm) was found from  $V_1$  (BARI Tomato 15) 123 and the shortest plant (29.53 cm) was found from variety V<sub>3</sub> (BARI Tomato 2). At 45 DAT, the highest 124 plant height (53.77 cm) was recorded from V<sub>1</sub>, while the lowest (48.48 cm) was recorded from V<sub>3</sub>. The 125 plant height ranged from 70.31 cm to 75.33 cm at 60 DAT. The longest plant (75.33 cm) was recorded from  $V_1$  and the shortest plant (70.31 cm) was recorded from  $V_3$ . At final harvest, the highest plant 126 127 (78.12 cm) was recorded from  $V_1$ , while the lowest (71.88 cm) was recorded from  $V_3$ . Organic matter 128 improves soil structure, increases the water holding capacity and promotes biological transformations 129 such as N-mineralization and enhances crop growth and development [9]. The results of this study 130 are also in agreement with the findings of [10, 11].

The variation was found due to combined effect of organic manure and variety on plant height at 145 146 different days after transplanting (Table 1). The maximum plant height (48.80cm) was recorded from 147 the treatment combination of  $M_2V_1$ , while the treatment combination of  $M_0V_3$  gave the minimum plant 148 height (16.66 cm) at 30 DAT. At 45 DAT significant differences in terms of plant height was observed 149 among the treatment combinations. However the largest plant (75.08 cm) was recorded from the 150 treatment combination of  $M_2V_1$  whereas the minimum (36.20 cm) was recorded from treatment combination of  $M_0V_3$ . At 60 DAT, the tallest plant (90.61 cm) was recorded from the treatment 151 152 combination of  $M_2V_1$ , while the minimum plant height (51.22 cm) was recorded from treatment 153 combination of  $M_0V_3$ . At harvest the maximum plant height (97.80 cm) was obtained from the 154 treatment combination  $M_2V_1$  whereas the minimum (58.90 cm) was found from the treatment 155 combination of M<sub>0</sub>V<sub>3</sub>.

158 In a column, means followed by same letter (s) do not differ significantly at 5% level of probability,  $M_0$ 159 = Control,  $M_1$  = Cowdung (30 t.ha<sup>-1</sup>),  $M_2$  = Poultry manure (25 t.ha<sup>-1</sup>) and  $M_3$  = Vermicompost (20 t.ha<sup>-1</sup>), V1 = BARI tomato 15,  $V_2$  = BARI tomato 14 and  $V_3$  = BARI tomato 2

161

# 162 3.2 Number of flower clusters per plant163

Application of organic manures exhibited a significant influence on the number of flower cluster per tomato plant (Table 2). The maximum number of flower clusters per plant (9.74) was recorded from  $M_2$  (Poultry manure), which was statistically identical (8.89) to  $M_1$  while the minimum (8.27) was obtained from  $M_0$  (Control treatment).

168 A significant variation was recorded due to combined effect of different varieties on number of flower 169 clusters per plant under the present investigation (Table 2). The maximum number of flower cluster 170 per plant (10.61) was recorded from V<sub>1</sub> (BARI Tomato 15) and the minimum number of flower cluster 171 per plant (7.49) was obtained from V<sub>3</sub>.

172

179

The variation was found due to combined effect of organic manure and varieties for number of flower cluster per plant (Table 3). The maximum number of flower cluster per plant (11.64) was recorded from the treatment combination of  $M_2V_1$  (Poultry manure + BARI Tomato 15) which was statistically identical to  $M_2V_2$  (11.37) (Poultry manure + BARI Tomato 14), while the treatment combination of  $M_0V_3$  (Control + BARI Tomato 2) gave the minimum (6.34) number of flower clusters per plant. This study is almost similar to the findings of [**12**].

# 180 3.3 Number of flowers per cluster181

Number of flowers per cluster varied significantly due to the application of organic manures under the present study (Table 2). The maximum number of flower per cluster (9.24) was recorded from  $M_2$ (Poultry manure), while the minimum (8.41) was obtained from control ( $M_0$ ). These findings are similar to the findings [9, 11].

186 Different varieties showed significant variation on number of flowers per cluster under the present trial 187 (Table 2). The maximum number of flower per cluster (10.52) was recorded from V<sub>1</sub> (BARI Tomato 188 15) which was statistically similar to V<sub>2</sub> (BARI Tomato 14) and the minimum number of flowers per 189 cluster (7.07) was found from V<sub>3</sub> (BARI Tomato 2).

190

198

The variation was also found due to combined effect of organic manures and varieties on number of flowers per cluster per tomato plant (Table 3). The maximum number of flower per cluster (11.43) was recorded from treatment combination of  $M_2V_1$  (Poultry manure + BARI Tomato 15), while the treatment combination of  $M_0V_3$  (Control + BARI Tomato 2) gave the minimum number of flowers per cluster (5.58).

# 197 3.4 Number of flowers per plant

199 Number of flowers per plant varied significantly due to application of different organic manures (Table 200 2). The maximum number of flowers per plant (58.25) was recorded from  $M_2$  (Poultry manure), while 201 the minimum (36.11) was obtained from control treatment ( $M_0$ ).

Different varieties showed significant variation on number of flowers per plant under the present investigation (Table 2). The maximum number of flower per plant (48.05) was recorded from V<sub>1</sub> (BARI Tomato 15) and the minimum number of flower per plant (44.47) was found from V<sub>3</sub> (BARI Tomato 2). Application of manure facilitates slow release of nutrients and facilitates better nutrient uptake and assimilation during reproductive growth which might be the reason for higher number of flower per plant of tomato [11].

208

The variation was found due to combined effect of organic manures and varieties on number of flowers per plant (Table 3). The maximum number of flower per plant (91.16) was recorded from the treatment combination of  $M_2V_1$  (Poultry manure + BARI Tomato 15), while the treatment combination of  $M_0V_3$  (Control +BARI Tomato 2) performed the minimum number of flower per plant (26.40).

## 215 3.5 Number of fruits per plant

217 Number of fruits per plant differed significantly by application of different organic manures under the 218 present investigation (Table2). The maximum (42.07) number of fruits per plant was recorded from M<sub>2</sub> 219 (Poultry manure), while the minimum (26.83) was recorded from M<sub>0</sub> (Control treatment). It was 220 revealed that number of fruits per plant increased in poultry manure. This might be caused that Poultry manure contents high amount of nitrogen and nitrogen enhance photosynthesis, cell division 221 222 and cell enlargement. Similar trend of the results were found by [13] who reported that application of 223 manure improves microbial population and facilitates better nutrient uptake and increased the number 224 of fruits per plant. 225

226 Different varieties showed significant variation on number of fruits per plant under the present trial 227 (Table 2). The maximum (36.65) number of fruit per plant was recorded from V<sub>1</sub> (BARI Tomato 15) 228 and the minimum (31.63) number of fruits per plant was observed in V<sub>3</sub> (BARI Tomato 2). The reports 229 also supported by the results of [**5**, **9**, **11**].

Significant differences on number of fruits per plant were recorded due to the combined effect of organic manures and varieties (Table 3). The maximum (55.91) number of fruit per plant was recorded from treatment combination of  $M_2V_1$  (Poultry manure + BARI Tomato 15), while the treatment combination  $M_0V_3$  (Control +BARI Tomato 2) gave the minimum (15.70) number of fruits per plant.

# 250 3.6 Length of individual fruit (cm)

251

Length of individual fruit varied significantly for different organic manures (Table 4). The maximum length of individual fruit (7.97 cm) was recorded from  $M_2$  (Poultry manure), while the minimum (6.29 cm) was recorded from  $M_0$  (Control) which was statistically identical (7.71 cm) to  $M_3$  (Vermicompost). Similar types of results can be found by [**14**, **15**].

257 Different varieties showed significant variation on length of individual fruit under the present 258 investigation (Table 4). The maximum (7.66 cm) length of individual fruit was recorded from V<sub>1</sub> (BARI 259 Tomato 15) and the minimum (6.66 cm) length of individual fruit was obtained from V<sub>3</sub> (BARI Tomato 260 2).

The variation was found due to combined effect of organic manures and varieties for length of individual fruit under the present trial (Table 5). The maximum (10.94 cm) length of individual fruit was recorded from treatment combination of  $M_2V_1$  (Poultry manure + BARI tomato 15), while the treatment combination of  $M_0V_3$  (Control treatment + BARI Tomato 2) performed the minimum (4.08 cm) length of individual fruit.

## 267 **3.7 Diameter of individual fruit (cm)**

Diameter of individual fruit significantly influence by different organic manures (Table 4). The maximum (10.43 cm) diameter of individual fruit was recorded from  $M_2$  (Poultry manure), which was statistically identical with  $M_3$  (9.44 cm) and  $M_1$  (10.35), while the minimum (8.84 cm) was recorded from  $M_0$  (Control treatment). This trend is similar to [**16**, **17**].

273

266

268

274 Different varieties showed significant variation on diameter of individual fruit under the present 275 investigation (Table 4). The maximum (10.18cm) diameter of individual fruit was recorded from V<sub>1</sub> 276 (BARI Tomato 15) and the minimum (9.18cm) diameter of individual fruit was obtained from V<sub>3</sub> (BARI 277 Tomato 2).

278

279 Combined effect of organic manure and varieties varied significantly on diameter of individual fruit 280 (Table 5). The maximum (13.31 cm) diameter of individual fruit was recorded from treatment 281 combination of  $M_2V_1$  (Poultry manure + BARI Tomato 15), while the treatment combination of  $M_0V_3$ 282 (Control treatment + BARI Tomato 2) gave the minimum (6.60 cm) diameter of individual fruit. Our 283 findings are in agreement with the findings of [**18**].

# 285 3.8 Weight of individual fruit (g)

286

287 Weight of individual fruit varied significantly due to application of different organic manures (Table 4). 288 The maximum (123.33 g) weight of individual fruit was recorded from  $M_2$  (Poultry manure), while the 289 minimum (91.69g) was recorded from  $M_0$  (Control treatment). 290

A significant variation found different varieties on weight of individual fruit under the present trial (Table 4). The maximum (134.58 g) weight of individual fruit was recorded from V<sub>1</sub> (BARI Tomato 15) and the minimum (99.18 g) weight of individual fruit was recorded from V<sub>3</sub> (BARI Tomato 2).

The variation was found due to combined effect of organic manures and varieties on weight of individual fruit (Table 5) The maximum (176.66 g) weight of individual fruit was recorded from treatment combination of  $M_2V_1$  (Poultry manure + BARI Tomato 15), while the treatment combination of  $M_0V_3$  (Control treatment + BARI Tomato 2) performed the minimum (73.41 g) weight of individual fruit. Application of manures supply slow release of nutrients and increase the accumulation of carbohydrates which might be the reason for higher individual fruit weight. This was supported by [**19**, **20**, **21**].

# 303 3.9 Yield (kg.plant<sup>-1</sup>)

305 Yield per plant varied significantly due to application of different organic manures (Table 4). The 306 maximum (2.06 kg.plant<sup>-1</sup>) yield was recorded from  $M_2$  (Poultry manure), while the minimum (0.99 307 kg.plant<sup>-1</sup>) was found from  $M_0$  (Control treatment). Poultry manure is rich in its nitrogen and nutrients 308 content. These favorable conditions creates better nutrients absorption and favors the growth and 309 development of root system which in true reflects better vegetative growth, photosynthetic activity. 310 Consequently higher total yield would be obtained by poultry manure. The results also agreed to the 311 findings of [**22**].

313 Different varieties showed significant variation on yield per plant under the present investigation 314 (Table 4). The maximum (1.75 kg.plant<sup>1</sup>) yield was recorded from V<sub>1</sub> (BARI Tomato 15) and the 315 minimum (1.37 kg.plant<sup>1</sup>) yield was obtained from V<sub>3</sub> (BARI Tomato2). Similar trend of results were 316 found by [**23**]. 317

The variation was found due to interaction effect of organic manures and varieties for yield per plant (Table 5). The maximum (2.07 kg.plant<sup>1</sup>) yield was recorded from treatment combination of  $M_2V_1$ (Poultry manure + BARI Tomato 15), while the treatment combination  $M_0V_3$  (Control treatment + BARI Tomato 2) gave the minimum yield (0.75 kg.plant<sup>1</sup>). Application of organic manure supply plant nutrients including micronutrients, improve soil physical properties like structure, water holding capacity, increase the availability of nutrients and favors the beneficial microorganisms which positively increase the yield and quality of tomato [**24,25**].

## 344 4. CONCLUSION

REFERENCES

In this study, organic manures played a significant role in enhanced growth and yield performance of tomato in sustainable production system. BARI Tomato 15 coupled with poultry manure enhanced vegetative and reproductive growth with higher yield of tomato by slow and steady release of nutrients to the plants compared to other treatments. Thus the application of BARI Tomato 15 coupled with poultry manure can reduce the cultivation cost of tomato while minimizing pollution by excessive use synthetic fertilizers and could be considered as a good production strategy for obtaining high yields with lower impact on the environment.
