

**The effect of different energy source on the growth performance of *Clarias gariepinus* fingerlings**

**ABSTRACT**

This study was aimed to evaluate and compare the effects of different selected energy feed stuff namely; Maize (DT<sub>1</sub>), Guinea corn (DT<sub>2</sub>), millet (DT<sub>3</sub>), and wheat (DT<sub>4</sub>) on the growth performance and body composition of African sharptooth catfish (*Clarias gariepinus* Burchell) fingerlings. This energy feedstuff in addition with other feed ingredients was used to formulate four (4) isonitrogenous and isoenergy diets at 40% crude protein. The energy feedstuffs were formulated at 36.31%, 38.26%, 37.09% and 40.05% level of inclusion respectively. The experiment in the ponds used a set of 2 hapas with mesh size 2mm in each pond measuring 1.62m<sup>2</sup>, therefore replicating the experiment 2 times in a completely randomized design. The evaluation of the physical parameters revealed that there was no significant difference ( $p>0.05$ ) in moisture, ash, lipid, fibre, protein and nitrogen free extract among the treatment (diets). The diet with maize (DT<sub>1</sub>) has the highest growth rate followed by diet containing millet (DT<sub>3</sub>), guinea corn (DT<sub>2</sub>) and diet containing wheat (DT<sub>4</sub>) had the lowest growth rate. This study, revealed that, among the energy feedstuffs evaluated maize (DT<sub>1</sub>) produced better growth parameters and could be recommended for on-farm aqua-feed.

**Keywords:** *Clarias gariepinus*, energy source, fingerlings, maize, Guinea corn, Millet, wheat.

**INTRODUCTION**

28 Every living organism including fish requires food for growth, reproduction and maintenance of  
29 tissues. To sustain fish under culture, supplemental diet must be provided to complement natural  
30 feed supply [1]. Feed stuffs used in aquaculture to provide basic nutrients such as protein,  
31 carbohydrate, minerals, water, vitamins and lipids are expensive because of their competitive uses  
32 by man and other animals [2]. Research has therefore focused on the need to provide alternative  
33 sources of these essential nutrients for use in aqua-feeds.

34 Aquaculture requires optimization of nutrition to efficiently raise fish for food production [3].  
35 Nutrition have been reported by Adewolu and Adoti [4] to play a critical role in intensive aquaculture  
36 as it influences production cost as well as fish growth, health and waste production. Fish nutrition is  
37 the study of nutrients and energy sources essential for fish health, growth and reproduction [4]. Fish  
38 requires high quality nutritionally balanced diet for growth and for the attainment of market size  
39 within the shortest possible time [5]. Catfish farming has continued to attract private sector initiative  
40 compared to earlier public or government-sponsored programmes [6]. *Clarias gariepinus* is regarded  
41 as a good prospect for aquaculture due to its outstanding culture characteristics such as ability to  
42 adapt adverse environmental conditions, efficient utilization of various types of locally formulated  
43 fish feed, resistance to diseases, high economic potential and simple techniques in the propagation  
44 of their fingerlings [7].

45 Carbohydrate is a cheap source of dietary energy in domestic animals including fish [8].  
46 Carbohydrates are important non-protein energy sources for fish and should be included in the diets  
47 at appropriate levels in order to maximize the use of dietary protein for growth. The amount of non-  
48 protein energy sources that can be incorporated into fish diets is not fully understood because  
49 certain fish species exhibit reduced growth rates when fed with carbohydrate free diets [9].

50 The purpose of this study is to determine the effect of different energy sources on the growth  
51 performance of *Clarias gariepinus* fingerlings.

52  
53  
54

## 55 **MATERIALS AND METHODS**

56

57 The experiment was carried out at the Fish farm of the Institute of Oceanography, University of  
58 Calabar, Calabar for 56 days. Two hundred and five (205) fingerlings of *Clarias gariepinus* with  
59 mean weight of  $4.68 \pm 0.093$ g were collected from the University of Calabar Fish Farm and  
60 acclimatized for seven (7) days. Before stocking, the initial weight (g) and length (cm) of the

61 fingerlings were weighed to the nearest 0.1g using Metlar -200D electronic weighing balance and  
62 nearest 0.1cm measuring board for length. Five fingerlings were randomly picked and taken to the  
63 laboratory for proximate analysis prior to feeding trials. During the period of acclimatization, the fish  
64 were fed with 1.5mm Copen feed. The experiment in the ponds used a set of 2 hapas with mesh  
65 size 2mm in each pond measuring 1.62m<sup>2</sup>, therefore replicating the experiment 2 times in a  
66 completely randomized design i.e 2 hapas in each of the four earthen ponds that were assigned for  
67 the study. The fingerlings were randomly distributed in 25 numbers to all hapas unit. Feed  
68 ingredients used for the feed formulation (maize, guinea corn, millet, wheat, soybeans, fish meal  
69 and mineral premix) were purchased from Watt market Calabar, Nigeria. feed stuff/ingredient such  
70 as soybeans was processed by toasting to improve their digestibility and eliminate anti-nutritional  
71 factor that may be present in the feed.

72

### 73 **Formulation of feed**

74 Pearson's square method was employed to formulate the four isonitrogenous and isoenergetic  
75 experimental diets at 40% crude protein. Each of the diets contain only one of the test grains at  
76 36.31%, 38. 26%, 37.09% and 40.05% level of inclusion (Table 1)

77 Fish were fed twice a day for eight weeks at 5% of their body weight; the amount of feed given was  
78 adjusted after the weekly measurement. The growth parameters were evaluated as given below.

79

80 Mean weight gain (MWG) = MFW – MIW

81

82 Where, MWG = Mean Weight Gain, MFW = Mean Final Weight and MIW = Mean Initial Weight

83

84 Specific growth rate (SGR): was established from the relationship of the differences in weight  
85 periods.

86

$$87 \text{ SGR} = \frac{\log_e W_2 - \log_e W_1}{T} \times 100$$

87

88 Where: W<sub>1</sub> = weight (g) at stocking, W<sub>2</sub> = weight (g) at the end of experiment, T = time duration (in  
89 days) of the experiment and Log<sub>e</sub> = natural logarithms

90

91 Feed conversion ratio (FCR): was determined from the relationship of feed intake and wet weight  
92 gain.

93

$$94 \text{ FCR} = \frac{\text{Amount of fed given (g)}}{\text{Increase of fish weight (g)}}$$

95

96 Protein Efficiency Ratio (PER): was determined from the relationship between weight gain and  
97 protein consumed.

98

$$\text{PER} = \frac{\text{Increase of fish weight}}{\text{protein intake}}$$

99

100 **Apparent Net Protein Utilization (ANPU):** was determined as follows:

101

$$\text{ANPU} = \frac{\text{Protein gain}}{\text{protein intake}} \times 100$$

102

103

#### 104 **Proximate analysis**

105

106 The proximate composition of the formulated diet and the proximate composition of the initial and  
107 final carcass of the experimental fish were determined according to methods described by AOAC  
108 [10].

109

110

#### 111 **Statistical analysis**

112

113 Data generated were analysed using One-way ANOVA to test for significance using PASW windows  
114 software (predictive analytical software) program (version 19.0). Effects with a probability of  $P < 0.05$   
115 were considered significant whereas the probability of  $P > 0.05$  was not considered significant.

116

117

118

119

## 120 RESULTS AND DISCUSSION

121 The proximate compositions of experimental diet and experimental fish are shown in Tables 2 and  
122 3, respectively. From Table 2, it was observed that, the crude protein level of the four experimental  
123 diets differs significantly (i.e.  $42.11 \pm 0.01$ ,  $40.58 \pm 0.01$ ,  $41.72 \pm 0.01$ , and  $40.24 \pm 0.01$   
124 respectively). The ratio in Table 3 shows that the composition of the experimental fish feed and the  
125 diets of various energy sources did not vary significantly at 5% level of significance. The growth  
126 performance and nutrient utilization of the fish samples in table 3 indicated that diet 1 had the  
127 highest weight gain (18.91g) and highest specific growth rate (2.76%) while diet 4 had the lowest  
128 weight gain (11.16g) and lowest specific growth rate (2.54%). The protein efficiency ratio (PER)  
129 values ranged between  $0.16 \pm 0.01$  and  $0.19 \pm 0.02$ . Diet3 (DT<sub>3</sub>) composed of millet recorded the  
130 highest protein efficiency ratio ( $0.19 \pm 0.02$ ) while Diet2 (DT<sub>2</sub>) composed of guinea corn recorded the  
131 lowest protein efficiency ratio ( $0.16 \pm 0.01$ ). The feed conversion ratio (FCR) values ranged between  
132  $13.57 \pm 1.14$  and  $15.99 \pm 0.56$ . Diet2 (DT<sub>2</sub>) recorded the highest feed conversion ratio ( $15.99 \pm 0.56$ ).  
133 While, Diet3 (DT<sub>3</sub>) recorded the lowest feed conversion ratio been  $13.57 \pm 1.14$ . The feed conversion  
134 efficiency (FCE) values ranged between  $6.05 \pm 0.00$  and  $7.45 \pm 0.65$ . Diet3 recorded the highest feed  
135 conversion efficiency ( $7.45 \pm 0.65$ ) while, Diet2 (DT<sub>2</sub>) recorded the lowest feed conversion  
136 ( $6.05 \pm 0.07$ ).

137 Carbohydrate, either of cereal or tuber in fish feed has been reported to acts as both structural  
138 and energy component [11], which have some influence on the rate of growth of fish provided all  
139 other physiological requirements are satisfied [12]. The isonitrogenous and isoenergetic  
140 experimental diets were formulated at 40% crude protein and 36.31%, 38.26%, 37.09% and 40.05%  
141 level of inclusion of maize, guinea corn, millet, wheat based on the fact that *Clarias gariepinus* is an  
142 omnivore, emphasizing animal source of food, therefore its feed contains less carbohydrates  
143 compare to plant based omnivore like "tilapia".

144 In the research conducted by Al-Ogaily et al. [13] using maize, wheat, barley, rice and sorghum  
145 at 25% level of inclusion and approximately 41% crude protein, the diet containing sorghum gave  
146 the best performance at 5% level of significance ( $p < 0.05$ ), while there was no significant difference  
147 ( $p > 0.05$ ) in the performance of maize, wheat, and rice. The slight difference in the result of Al-Ogaily  
148 et al. [13] and the present study may be due to the different levels of inclusion of the grain. As the  
149 levels of inclusion of the grain increased, the digestibility of sorghum reduces at higher rate than that  
150 of maize. This is due to the presence of anti nutritive factor, tannin [14]; [15], in untreated sorghum  
151 and its influence on diet increase with increasing level of sorghum in the diet.

## 152 Conclusion

153 This study discovered the importance of maize, guinea corn, millet, wheat which can be utilized  
154 efficiently in *Clarias* diet to enhance growth and body composition quantity or quality. This study will  
155 help the researchers to identify the level of inclusion of different energy sources that many  
156 researchers were not able to explore. It is also recommended that for practical purpose, lower level  
157 of inclusion of grains than the 36.31%, 38.26%, 37.37% and 40.05% be used in *Clarias* diet.

## 158 **ETHICAL APPROVAL**

159 As per international standard or university standard ethical approval has been collected and  
160 preserved by the authors.
