

Litter under Potential Eucalypts Genotype Stands in Eldorado do Sul, Rio Grande do Sul, Brazil

ABSTRACT

The objective of the study was to quantify the litter in different genotypes of eucalyptus stands at 49-months-old, located in Eldorado do Sul, Rio Grande do Sul, Brazil. Areas of 720 m² were demarcated for each genotype. In each area, 15 samples were randomly collected. The litter ranged from 4.51 to 10.77 Mg ha⁻¹, highlighting the *E. dunnii* and the hybrid of *E. urophyllax* *E. globulus* with the lowest and largest accumulation, respectively. The leaves corresponded, on average, between 48.56% and 73.03% of the total litter. The differentiation between the genotypes occurred as to the accumulated litter.

Keywords: Litter, Leaves, *Eucalyptus* genotypes stands, Sustainability.

1. INTRODUCTION

Tree plantations stabilish many beneficial ecological interactions with the ecosystem, such as watershed protection, increased organic matter and soil nutritional status [1]. This dynamic is represented by the deposition of litter as input and by the deposition as output. It is essential for the maintenance of forests or forest stands [2], especially in highly weathered soils, where plant biomass is the main nutrient reservoir [3].

24 The litter on the soil is used in the cycling of biogeochemical
25 nutrients. Afterwards, the decomposition and the release of the constituent minerals will
26 be absorbed by the roots of the plants. This process also will increase the organic matter
27 content in the soil [4]. In this context, nutrient return via litter is the most important
28 route of the biogeochemical cycle [3].

29 In general, the increase of the litter deposition above the soil is observed after the
30 age of maturity of the trees, when the tree canopy is closed. Ended this phase, a slight
31 decrease or stabilization in the deposition may be observed [5].

32 The accumulation of litter varies according with the origin, species, forest cover,
33 successional stage, age, collection season, forest type and site. Moreover, factors
34 like: edaphoclimatic conditions, index site, understory, silvicultural management and
35 proportion of canopy. The litter decomposition also is influenced by natural disturbances
36 such as fire, insect or artificial attack [6].

37 The litter deposition is higher in the period of greater physiological activity of the
38 individuals, causing an intensification of foliage exchange and senescent material
39 release, so it will give place a new and photosynthetically more active foliage [7].

40 Knowledge of the amount of litter in different eucalyptus species and provenances
41 is of fundamental importance in order to maintain a sustainable management of soils
42 and mineral resources [8].

43

44

45 The present study had as objective to estimate the litter in different *Eucalyptus*
46 genotypes established in Eldorado do Sul, Rio Grande do Sul, Brazil.

47

48

49 **2. MATERIALS AND METHODS**

50 The research was developed with six different genotypes of eucalypts (Table 1),
 51 in an area belonging to the company CeluloseRiograndense - CMPC, in the city of
 52 Eldorado do Sul, RS, Brazil (Figure 1). The area is under the geographic coordinates of
 53 30 ° 11'303 "south latitude and 51 ° 37'477" west longitude.

54

55 **Table 1. Characterization of the studied genotypes**

Genotypes	Age	Spacing	G
	(months)	(m)	(m ² ha ⁻¹)
<i>E. benthamii</i> (Provenance 1)	49	3 x 3	24,4
<i>E. benthamii</i> (Provenance 2)	49	3 x 3	22,7
<i>E. saligna</i>	49	3 x 3	23,7
<i>E. dunnii</i>	49	3 x 3	16,7

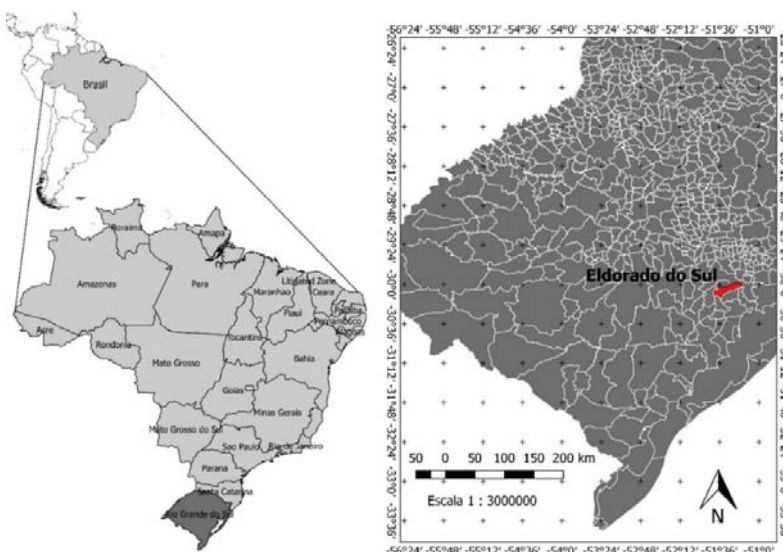

Figure 1. Location of the municipality of Eldorado do Sul, Rio Grande do Sul, Brazil

The climate is characterized as subtropical humid (Cfa), according to the climatic classification of Köppen, presenting average temperature corresponding to 19 °C. The average annual precipitation is equal to 1,400 mm [9].

The soil in the area is classified as Red-Yellow Argisol. Table 2 presents the chemical and physical attributes of the soil depths from 0 to 130 cm.

77 CTC

78

79 In the preparation of the area, the subsoiling was performed at a depth of 60 cm,
80 whereassurface limingwas realized with 2 Mg ha⁻¹ of limestone, and 200 kg ha⁻¹ of
81 single superphosphate. The fertilizer used during planting consisted of 110 g plant⁻¹ of
82 N-P₂O₅-K₂O (06:30:06) + 0.3% Zn and 0.2% Cu. For coverage fertilization 200 kg ha⁻¹
83 of N-P₂O₅-K₂O (12:00:20) + 0.7% of B were applied, and for the maintenance
84 fertilization, 300 kg ha⁻¹ of N-P₂O₅-K₂O (24:00:26) + 0,5% B were applied.

85 The litter collections were carried out in June 2016. In thisstudy, a plot of 720 m²
86 was stabilished, where 15 samples were collected, randomly, totaling 90 samples.

87 The litter sampling wasdoneusing an iron frame (Figure 2) of 0.25 m x 0.25 m
88 (0.0625 m²).It was placed on the surface of the land, and all the organic material present
89 in its soil. After collection, the sampled materials were stored in plastic bags and
90 theysent to the laboratory where they were separated in the following: leaves, branches
91 and miscellaneous (peels, reproductive materials and non-identifiable residues).

92 Subsequently, the fractions were placed in paper containers fordrying in a
93 circulation oven and air renovation at 70 °C until weight stabilization. Finally, the
94 samples were weighed in a precision scale (0.01 g) and the dry weights were
95 extrapolated to values per hectare to obtain the mass of the litter.

Figure 2. A: Canopy of a stand of *Eucalyptus* sp.; B: Litter on the soil; and C: Sample of the litter on the soil for quantification.

Statistical analyzes were applied with the aid of the statistical program Assistat 7.7 © [10] at the level of 5% probability of error. The Tukey test was used for the comparison of means.

3. RESULTS AND DISCUSSION

In Table 3 it is possible to verify the distribution of litter for the different fractions of the studied genotypes. The litter was highest in hybrid *E. urophylla* x *E. globulus* (10.77 Mg ha⁻¹). *E. dunnii* (4.51 Mg ha⁻¹) showed lowest while *E. benthamii* (P1) reached intermediate values (8.38 Mg ha⁻¹).

125 **old**

126

Genotypes	Leaves	Miscellaneous	Branches	Total
	(Mg ha ⁻¹)			
<i>E. benthamii</i> (P1)	6.12ab *(2.15)	0.53a (0.45)	1.73bc (1.74)	8.38a (3.31)
<i>E. benthamii</i> (P2)	3.27cd (1.41)	0.65a (0.61)	1.14c (0.57)	5.06b (1.64)
<i>E. saligna</i>	4.63bc (1.26)	0.43a (0.25)	4.10a (2.59)	9.13a (3.04)
<i>E. dunnii</i>	2.19d (1.24)	0.95a (1.17)	1.46bc (1.35)	4.51b (2.81)
<i>E. urophylla</i> x <i>E. globulus</i>	6.72a (2.93)	0.32a (0.27)	3.82a (2.08)	10.77a (3.95)
<i>E. urophylla</i> x <i>E. grandis</i>	5.88ab (1.65)	0.53a (0.44)	3.11ab (2.03)	9.49a (2.87)
CV %	38.97	108.2	71.67	38.26

127 CV: Coefficient of variation.

128 Mean of each variable in the different treatments is followed by equal letters, so it does
129 not show significantly difference in the Tukey test at the 5% level of error. * Values in
130 parentheses are the standard deviation of the mean.

131

132 The litter showed a value lower than that found by Viera et al.[11], in a plantation
133 of hybrid *E. urophylla* x *E. globulus* at four-years-old in Eldorado do Sul, RS, Brazil
134 (14.0 Mg ha⁻¹). On the other hand, Schumacher et al.[8] studying stands of *E. grandis*, *E.*
135 *cloesiana* and *E. urophylla*, with nine-years-old in Santa Maria, RS, Brazil observed
136 values among 16.8, 16.5 and 12.6 Mg ha⁻¹ whereas Santos et al.[12] analyzing a stand of
137 *E. saligna* at four and five years of age in São Gabriel, RS, Brazil found values
138 respectively equal 12.76 and 12.00 Mg ha⁻¹. Lastly, Brun et al. [4] in a planting of *E.*
139 *uroglobulus*, with 5.5-years-old in Eldorado do Sul, RS, Brazil observed 19.5 Mg ha⁻¹ of
140 the litter.

141 In another stand of *E. grandis*, at seven-years-old, in Seropédica, RJ, Brazil, Reis
142 et al.[3] was reported an amount of 11.84 Mg ha⁻¹ litter. In the Southwest region of
143 Brazil, in different forest sites, Gama-Rodrigues et al.[13] evaluated litter in eucalypts
144 plantations, and then, they also observed that the amount of litter ranged from 4.2 to 37.6
145 Mg ha⁻¹ at seven-years-old. A similar result was found by Freitas et al.[14], in a stand of
146 *E. grandis*, at the nine-years-old, in the city of Alegrete, RS, Brazil (5.41 Mg ha⁻¹).

147 The production and accumulation of litter presents a significant variability, so this
148 difference can be due to the variation in the climatic conditions, the quality of the site, the
149 age of the stand, the characteristics of the species or the inclusion of the understory litter
150 and the degree of forest stability [3].

151 In relation to total litter, the hybrid *E. urophylla* x *E. globulus* presented
152 an accumulation of 58.12% and 53.02% higher for clones *E. dunnii* and *E. benthamii* (P2).
153 According to Freitas et al.[14], the litter rates accumulated in forest plantation soils can
154 vary significantly between different species in the same sites.

155 The leaves fraction corresponded on average, between 48.56% and 73.03% of the
 156 total litter (Figure 3). *E. dunnii* was the clone that presented the lowest percentage of
 157 leaves deposited among the species studied, and *E. benthamii* (P1) was the largest hybrid.
 158 The leaves usually constitute the largest proportion of the biomass of the residues
 159 falling on the soil. This proportion grows with age to a certain extent, and then
 160 it decreases due to the increase in the fall of branches and bark [3].

161

162

163 **Figure 3. Relative litter of different *Eucalyptus* genotypes**

164

165 In this context, Kleinpaul et al. [15] studied the litter in a twelve-year-old
 166 eucalypts stand and they observed that the branches presented greater accumulation on
 167 the ground, with 38.8%. According to the author, this occurred because the eucalypts
 168 stands suffer a more intense process of self-pruning, in relation to other species so it leads
 169 to greater accumulation of branches on the ground.

170 Schumacher et al.[8], studying the litter in three species of eucalypts (*E.*
171 *urophylla*, *E. cloesiana* and *E. grandis*), at nine-year-old, in Santa Maria, RS, Brazil,
172 observed that the branches fraction was the most representative in all species.
173 According to the authors this may mean a propensity of these species for the self-
174 pruning.

175 For the branches fraction, the highest yields occurred in the clones *E. saligna* and
176 *E. uroglobulus*, with 2.48 and 2.24 Mg ha⁻¹. Lower accumulation occurred in *E. dunnii*,
177 with 2.19 Mg ha⁻¹. The miscellaneous fraction varied from 0.32 to 0.95 Mg ha⁻¹.
178 It was the lowest value found in hybrid *E. urophylla* x *E. globulus*. The highest in *E.*
179 *dunnii* did not show statistically difference for other clones.

180 The existence of a significant variability in the accumulation of organic litter
181 blanket in relation to other works carried out with eucalypts species can be explained
182 based on the variation of climate, sites, age and forest density, different genetic
183 characteristics of each species and the stability achieved by the stand. Moreover, it
184 depends of the time elapsed since the last intervention that may have influenced the
185 litter. These factors will affect the balance between the amount of material deposited
186 and the time required for its decomposition, reflecting the greater or less accumulation
187 of litter in the forest soil and the percentage composition of the different fractions
188 that it composes then [8].

189

190 4. CONCLUSION

191 The highest amount of litter occurred in hybrid *E. urophylla* x *E. globulus*. It is
192 responsible to provide greater protection to the soil, however amount of the litter of litter
193 was lower for *E. dunnii*.

194 For all genetic materials studied, the leaves fraction presented the highest
195 contribution in the amount of the litter.

196 The differentiation between the genotypes occurred basically as to the accumulated
197 litter.
