| 2 3 4 5 | The Effect of Different Organic Nutrients on Some Quality Properties of Popcorn (<i>Zea mays</i> L. <i>everta</i>) | |
| 6 7 9 10 11 | ABSTRACT | |
| | Aims: Study was to aimed find out effect of different organic nutrients on some quality properties of popcorn. Study design: Trial was designed in complete randomized block design with tree replications. Ant-Cin-98 popcorn cultivar was used in the study. Each parcel comprised 4 lines. The planting was made into a depth of 5-6 cm along the lines 5 meters long with a row spacing of 70 cm and intra row of 20 cm. Place and Duration of Study: This study was conducted in Diyarbakır - Cermik conditions of Turkey between 2010 and 2011. Methodology: The effect of conventional and fifteen different organic materials (torf, compost, cattle manure, chicken manure, horse manure, sheep manure, pigeon manure, vermicompost, seaweed + cattle manure, compost + humic acid, cattle manure + humic acid, chicken manure + humic | Comment [MC1]: Introduce organic nutrirnts before aims |
| 12 | acid, torf + humic acid) to some quality parameters of popcorn were researched in the study. Results: According to the investigated results, the highest and the lowest values were ranked between 19.98% (torf + humic acid) and 17.26% (vermicompost) for cob ratio, 138.65 g (seaweed + cattle manure) and 122.48 g (chicken manure) for 1000-kernel weight, 81.29 kg hl ⁻¹ (horse manure + humic acid) and 75.62 kg hl ⁻¹ (vermicompost) for test weight, 19.71 cm ³ g ⁻¹ (torf) and 17.17 cm ³ g ⁻¹ (sheep manure + humic acid), for popping volume 5.92% (torf) and 3.65% (horse manure + humic acid) for number of unpopped kernel. Conclusion: Higher values obtained from organic nutrient sources than conversional application in all tested quality parameters. The implementation of organic fertilizers together with humic acid in popcorn produced better results in comparison to alone implementation of organic fertilizers. Also it was determined that using of natural enemies of <i>Trichogramma</i> spp against to corn borer can be possible without any chemicals. | Comment [MC2]: How? Explain methods |

14 **1. INTRODUCTION**

15

The corn is also used in human nutrition directly and indirectly in addition to the use as industrial raw material and animal feed in the world. Although dent corn (*Zea mays* L. *indentata*) varieties comprise the vast majority of corns grown both in world and in Turkey, no statistics related to the cultivation area, manufacture and consumption amount of popcorn (*Zea mays* L. *everta*) in Turkey. It is reported that planting is made around the provinces of Adana, Canakkale, Adapazari, Antalya, Isparta and Burdur, in Aegean and Mediterranean

22 Regions of Turkey [1]. Consumption of popcorn is increasing every passing day in Turkey.

23 The sub type of corn having grains popped when heated is popcorn. Popcorn is directly used 24 in human nutrition. It generates pressure inside the grain through expansion when the 25 humidity in the endosperm is heated because its grain is hard, its hull is thick and 26 impermeable. At the same time the starch in the endosperm transforms with the effect of 27 heat. The hull can't resist this pressure and bursts by splitting suddenly. The volume of the 28 grains burst expands and they are eaten by salting or adding oil. Its consumption rises also 29 in Turkey because of low cost and easy to prepare with popping machines, in pans or pots. 30 Popcorn is commonly consumed while watching cinema and soccer matches and television 31 during winter months. Additionally, it is preferred much by children [2].

Nowadays environmental pollution has reached a significant level as a result of the use of synthetic and chemical inputs in excessive amounts due to the production increase within conventional agriculture system. Organic fertilizers/matters, which are essential inputs of organic agriculture systems that have become widespread in parallel with the interest of people in organic products, are made available for producers under a great variety of names and contents in the market. It is necessary to utilize these matters in various ways to prevent environmental pollution caused by wastes, and to enhance organic matter level of our soil.

environmental politition caused by wastes, and to enhance organic matter rever of our

39 Different results have been obtained in studies conducted in different parts of the world 40 regarding the subject of the study. Anac and Okur [3] have reported that application of Biofarm (certified organic fertilizer) and farm fertilizer as organic fertilizer (uncertified) to trial 41 soil has led to significant increase in dry weight, mineral content and efficiency of corn 42 compared to control. Yazici and Kaynak [4] have reported that seaweed increases yield and 43 44 quality in organic farming, regulate the growth of plants, increase resistance to pests and diseases, improves the structure of the soil. Seker and Ersoy [5] have investigated the 45 effects of different doses of compost, cattle manure, chicken manure and leonardit on the 46 47 soil properties and the development of corn (Zea mays L.). They found as a result of the 48 research that type and dose of used organic fertilizer affects soil properties and the corn's 49 growth.

50 Shafiq et al. [6] have conducted a study to determine the effect of four organic (chicken 51 manure, farmyard manure, biofertilizer) and chemical fertilizer on efficiency and growth of 52 two maize varieties. The researchers have stated they have found parameters such as plant 53 height, seed number, 1000-kernel weight, grain yield and net profitability in the parcels 54 where chemical fertilizers were applied higher when compared to other parcels and this has 55 been followed by chicken manure applied parcels.

Selcuk and Tufenkci [7] have found that increasing humic acid application to corn has provided significant increase in number of grains per cob, cob length, plant height, 1000kernel weight and the number of cobs. Cengiz et al. [8] have conducted a study to determine the effect of synthetic and organic fertilizers on yield and quality of the corn plant. They have reported that according to the results obtained, the effect of organic preparations and organic fertilizers in the trials to yield and yield factors is at least as favorable commercial fertilizers.

In this study, it was aimed determining the effect of some organic nutritional sources (torf, compost, cattle manure, chicken manure, horse manure, sheep manure, pigeon manure, vermicompost, seaweed + cattle manure, compost + humic acid, cattle manure + humic acid, chicken manure, horse manure + humic acid, torf + humic acid) on some quality properties of second crop popcorn.

68 2. MATERIAL AND METHODS

69 2.1. Material

70 Experiment was conducted in Divarbakir province Cermik district under second crop

71 conditions. Ant-Cin-98 popcorn variety was used in the experiment. Organic nutrient sources 72

were used in the study (Table 1). Amount of total pure nitrogen both conventional and organic growing were 17 kg da⁻¹ based on the regulation, principles and applications of 73

74 organic agriculture in Turkey [9]. According to nitrogen content of organic material, maximum 75

pure nitrogen amount (17 kg da⁻¹) was calculated for organic applications (Table 1). For conventional applications total of 17 kg da⁻¹ nitrogen, 8 kg da⁻¹ phosphor and potassium (15-76

15-15 NPK as bottom fertilizer and urea as top fertilizer) were given as pure per decare. 77 Nitrogen content of nutritional sources used in the study and the amount of fertilizer thrown

78

79 per decare were given in Table 1.

80 Table 1. The nitrogen content of organic nutrient sources and applied amount

81

2.1.1. Climatic characteristics of the research area 82

83 Climate values of 2010 and 2011 in which the research was conducted with long years were given in Table 2. The average highest temperature (32.7 °C) was observed in July, the lowest 84 85 temperature (12.0 °C) in November between June-November months in 2010, and in 2011 the average highest temperature (31.5 °C) in July, the lowest temperature (6.6 °C) in 86 87 November in accordance with the data received from Divarbakir Regional Directorate of Meteorology. The highest value (61.8%) in terms of relative humidity occurred in October 88 89 2010, and the lowest value (22.3%) in August 2011. The water need of plants was met 90 through irrigation during the growing period.

91 2.1.2. Soil characteristics of the research area

92 Total salt content was found to be 0.03%, organic matter content 1.19%, lime rate 9.8%, 93 phosphor amount 2.75 kg da⁻¹, potassium amount 82.05 kg da⁻¹ and soil pH 7.4 in the soil 94 sample take from 0.30 cm soil depth in the place where trial was established in Diyarbakır 95 province Cermik district.

99 2.2. Method

122

123

124

Before the starting of experiment, the trial area was planted with wheat in 2008 and 2009 for making the area suitable for organic farming in which the trial would be established, and wheat was cultivated and harvested without application of any chemical fertilizer and agricultural pesticide. Physical and chemical properties of the trial area were determined by taking soil sample from a depth of 0-30 cm on the trial area before planting.

105 The soil was made ready for planting by processing with goble disc and then with disc 106 harrow prior to planting. The trial was established with three replicates according to 107 randomized complete block experimental design. Each parcel comprised 4 lines. The planting was made by hand into a depth of 5-6 cm along the lines 5 meters long with a row 108 109 spacing of 70 cm and intra row of 20 cm in 15-30 June. Most of the nutritional organic sources were applied with planting. Also some part of seaweed manure was applied before 110 planting and the rest as foliar fertilizer in three times. An equal amount of water was given to 111 the parcels with sprinkler irrigation after planting for germination, and furrow irrigation 112 throughout the growing period due to lack of moisture in sufficient levels for output. A space 113 114 of 2 meters was left between parcels to hinder water passage between parcels and the parcels were surrounded with berm. Cultural measures (tractor and hand hoeing) were 115 implemented to combat the weed. Chemical pesticides were not used in the search. 116 Trichogramma sp. predator that was obtained from Adana Agricultural Research Institute 117 Biological Control Unit was used within scope of biological control against Corn Cob Worm 118 119 which leads to great productivity losses for corn plants. Values were taken from two rows in the middle after discarding 0.5m from both beginnings and one rows situated at either sides 120 121 of the parcel as edge effect during the harvest between 20-25 September. Variance analysis

of the differences between averages were determined through Duncan multi comparison test [11]. In the study, the years were subjected to variance analysis separately and jointly.

was made with the values obtained by using Totemstat-C software package, the significance

125 3. RESULTS AND DISCUSSION

126

127 3.1. Cob Ratio (%)

Considering 2010-2011 year averages according to Table 3, cob ratio varied between
percent 17.26-19.98 in different nutrient applications. The highest cob ratio value was
determined to be 19.98% in torf + humic acid. The lowest cob ratio was obtained as 17.26%
from vermicompost application along combined averages in the trial.

137 3.2. 1000-Kernel Weight (g)

Considering 2010-2011 year averages according to Table 4, 1000-kernel weights varied 138 139 between 122.48-138.65 g in different nutrient applications. While the highest 1000-kernel 140 weight value was determined to be 138.65 g in seaweed manure + cattle manure, and 141 afterwards this was followed by horse manure + humic acid (137.41) with sheep manure +humic acid (137.11) respectively. In the meantime, conventional fertilizer application ranked 142 sixth among the applications with a 1000-kernel weight value of 132.41 g. The lowest 1000-143 kernel weight was obtained as 122.48 g from chicken manure application along combined 144 145 averages in the trial. In terms of 1000-kernel weight, we can say that the abundance of all applications in second year compared to the first year resulted from both climate and 146 environmental conditions and positive effect of nutritional sources. 147

148 The effect of nutritional sources plant on 1000-kernel weight in respect of corn plant was 149 given by obtaining different results in different studies. Prasanna et al. [12] have reported 150 that they received the highest 1000-kernel weight from vermicompost in respect of corn

- 151 plant, Shafig et al. [6] said that chemical fertilizer yielded 1000-kernel weight higher than 152 organic fertilizers (chicken manure, farmyard manure, bio-manure).
- 153 Table 4. 1000-kernel weight (g) values found in popcorn grown using different nutritional sources and the groups formed according to Duncan Test 154

157 \uparrow : $P \leq .01$, \ddagger : $P \leq .05$ ns: No significant

Various results were obtained in different studies carried out related to 1000-kernel weight in 158 159 popcorn. ldikut et al. [13] 114.9-122.9 g; Ertas et al. [14] 54.8-64.6 g; Gokmen et al. [15] 160 129.0-213.0 g; Ozkan [16] 127.0-133.0 g; Tekkanat and Soylu [17] 114.68-175.93 g; Oktem et al. [26] 291.0-342.0, Ozkaynak and Samancı [18] have reported 1000-kernel weight 161 varying between 86.0-140.0 g in lines, 83.0-115.0 g in hybrids. 162

3.3. Test weight (kg hl⁻¹) 163

164 Average values of the proportion of test weight determined in different nutritional sources in 165 popcorn grown organically between 2010 and 2011 and the groups formed according to 166 Duncan multi comparison test were given in Table 5.

Considering 2010-2011 year averages, test weight ranged from 75.62 kg hl⁻¹ and 81.29 kg 167 168 hl⁻¹ in different nutrient applications. When examined the Table 5, the highest test weight 169 value was 81.29 kg hl⁻¹ in horse manure + humic acid application, and afterwards respectively, torf + humic acid (80.58 kg hl⁻¹) and sheep manure + humic acid (80.56 kg hl⁻¹) 170 171 applications. Meanwhile, the lowest test weight was obtained as 75.62 kg h⁻¹ from vermicompost. The difference of nutrient elements in the structure of organic and 172 conventional nutritional sources at the end of the study, was seen affecting these fertilizer 173 sources at different levels. In the trial, the difference among fertilizer applications was found 174 to be statistically significant. 175

176 As a result, the highest test weight of the parcel is administered with a growth regulator of

177 humic acid organic fertilizer is taken. The studies have shown that humic acids in plant dry 178 weight effects are available. Some researchers reported that fresh and dry weights

179 increased significantly (P < .05) with treated humic acid at different levels compared to

180 control [6, 19, 20]. Asli and Neuman [21] reported that the humic acids reduce the dry weight

181 of corn.

3.4. Popping Volume (cm³ g⁻¹) 187

188 Considering 2010-2011 year averages according to Table 6, popping volume varied between 17.17 cm³ g⁻¹- 19.71 cm³ g⁻¹ in different nutrient applications. When examined the Table 6, the highest popping volume value was 19.71 cm³ g⁻¹ in torf application, and afterwards 189 190 respectively, vermicompost (19.41 cm³ g⁻¹) and pigeon manure (18.98 cm³ g⁻¹) applications. 191 Meanwhile, the lowest popping volume was obtained as 17.17 cm³ g⁻¹ from sheep manure + 192 humic acid. The difference of nutrient elements in the structure of organic and conventional 193 nutritional sources at the end of the study, was seen affecting these fertilizer sources at 194 195 different levels.

196 Besides, even though no study has been carried out about popping volume in organic popcorn, different study results obtained related to popping volume as 19.79-22.92 cm³ g 197 198 [14]; 19.67-25.33 cm³ g⁻¹ [18]; 18.50-35.25 cm³ g⁻¹ [17]; 21.0-27.5 cm³ g⁻¹ [22]; 28.1-28.7 cm³ 199 g⁻¹ [16] have a nature supporting our research results.

205 3.5. Number of Unpopped kernel (%)

Average values of number of unpopped kernel determined in different nutritional sources in 206 popcorn grown organically between 2010 and 2011 and the groups formed according to 207 208 Duncan multi comparison test were given in Table 7. Considering 2010-2011 year averages, 209 number of unpopped kernel ranged from 3.65% to 5.92% in different nutrient applications. When examined the Table 7, the highest number of unpopped kernel value was 5.92% in 210 211 peat application, and afterwards respectively, chicken manure (5.63%) and compost (5.16%) applications. Meanwhile, the lowest number of unpopped kernel was obtained as 3.65 % 212 213 from horse manure + humic acid. The difference of nutrient elements in the structure of organic and conventional nutritional sources at the end of the study, was seen affecting 214 215 these fertilizer sources at different levels. In the trial, the difference among fertilizer 216 applications was found to be statistically significant.

Besides, even though no study has been carried out about number of unpopped kernel in organic popcorn, different study results obtained related to non-popped grain rates as 12.43-16.91% [14], 3.49-12.19% in lines and 6.33-9.94% in hybrids [18]; 2.42-9.90% [17]; 2.77-3.48% [16], have a nature supporting our research results. Many researchers [14, 24, 25] have found significant differences in non-popped grain rate which is among major quality parameters of popcorn, and they reported that the impact of varieties had a largest share in this situation.

230

231 4. CONCLUSION

232

233 It has been determined with this study that organic popcorn production can be made also by 234 using different nutritional sources under Diyarbakır ecological conditions. It has been 235 ascertained that Ant-Cin-98 popcorn variety used in the trial can also be included in crop 236 rotation systems across in south eastern Anatolia region. Higher values obtained from 237 organic nutrient sources than conversional application in all tested quality parameters. 238 Furthermore, it was observed that the implementation of organic fertilizers together with 239 humic acid in popcorn produced better results in comparison to alone implementation of 240 organic fertilizers. It has been proved that corn production can be made without the use of chemical pesticides in the trial. Trichogramma sp. beneficial insects can be introduced to 241 242 local farmers and its use may be encouraged on corn planted areas. 243
