**Original Research Article** 

## Antioxidants and Radical Scavenging Activities of Nigeria Soybeans (*Glycine max* (L.)

5 6

1 2

## 7 ABSTRACT

Aim:To evaluated the antioxidant and radical scavenging ability of three different accessions
 (TGx-1835-10E, TGx-1987-62F and TGx 1951-3F) of soybean.

**Study Design:** *In vitro* evaluation of antioxidant assays: Total phenol, Total flavonoid, Total antioxidant capacity, Ferric reducing antioxidant capacity, Cupric reducing antioxidant capacity, Ferrous Ion-chelating Ability, DPPH and NO radical scavenging activities.

**Place and Duration:** Department of Biochemistry, Obafemi Awolowo University, Ile-Ife, Nigeria

15 (August–December, 2016).

**Methodology:** Hydroalcoholic crude extracts of TGx-1835-10E, TGx-1987-62F and TGx 1951-3F were obtained through soxhlet apparatus using 80% methanol and concentrated in a rotary evaporator at 40°C. The crude extract was then subjected to different complementary antiradical scavenging assays (Total phenol, Total flavonoid, Total antioxidant capacity, Ferric reducing antioxidant capacity, Cupric reducing antioxidant capacity, Ferrous Ion-chelating Ability , DPPH and NO radical scavenging activities.) following standard procedures.

Results: The results shows that TGx 1951-3F elicited the highest DPPH and NO radical 23 scavenging activity with IC<sub>50</sub> value of  $2.61\pm0.02$  mg/ml and  $2.58\pm0.02$  mg/ml, compared to 24 25 TGx-1835-10E and TGx-1987-62F. Similarly, Ferrous Ion-chelating Ability (FIC) of TGx 26 1951-3F was higher with IC<sub>50</sub> value of 1.38  $\pm$  0.07 mg/ml, compared to TGx-1835-10E and TGx-1987-62F with an IC<sub>50</sub> of  $1.86 \pm 0.16$  and  $2.07 \pm 0.16$  mg/ml. The reducing power of the 27 three accessions expressed in terms of ascorbic acid equivalent tested using FRAP, TAC 28 29 and CUPRAC assays showed that TGx 1951-3F has highest antioxidant activity follow by 30 TGx-1835-10E and TGx-1987-62F. This same trend was also observed in antioxidant 31 constituent present in the samples as TGx-1951-3F has higher phenolic and flavonoid content compared to TGx-1835-10E and TGx-1987-62F. 32

**Conclusion:** The result of this present study revealed that Accession TGx 1951-3F elicit the highest antioxidant potential nevertheless, accessions TGx-1835-10E and TGx-1987-62F also contain significant amounts of flavonoids and phenolic compounds. Consequently, making the plant seeds an important source of natural antioxidant, and might be helpful in prevention and management of various diseases associated with oxidative stress.

## 42 1. INTRODUCTION

43

Soybeans (Glycine max L.) is a legume that is universally consumed. Soybeans is a 44 45 complex food matrix containing no or low starch, 9% water, 30% carbohydrates, 20% total 46 fat and 36% protein in addition to wide arrays of bioactive phytochemicals like isoflavones. 47 lunasin, saponin, and trypsin inhibitors [1]. Recently there is a growing interest in Soybeans 48 by researchers owing to its potential role in the prevention of a number of chronic 49 degenerative diseases like cancer, coronary heart disease and osteoporosis [2]. 50 Consumption of sovbeans have become so widely important in recent times because of it human benefit such as protect heart health, defend against cancer, reduce the effects 51 52 of menopause, improve digestive health, reduce risk of hypertension and decrease the risk of diabetes which was adduced to the present of phenolic, isoflavone [3-4]. Bioactive phytochemicals present in soybeans differ greatly with the cultivar, weather and geographical planting location [5-6]. It has been recorded that Indian cultivars are rich in genistein content compared to the European and American soybean cultivars. [7].

Reactive oxygen species (ROS) and free radicals are constantly produced in pathological 57 58 conditions and has become a normal physiological bane [8]. Reactive species such as hydroxyl radical (OH), hydrogen peroxide, superoxide anions (O2-), and nitric oxide react 59 60 with DNA, proteins, and lipids that eventually lead to cell death and tissue damage [9]. Free radicals play a crucial role in the pathogenesis of aging, anemia, arthritis, asthma, 61 atherosclerosis, cancer, cardiovascular diseases, diabetes, hypertension, inflammation, 62 63 myocardial infarction, and neurodegenerative diseases [10]. Naturally all organism possess defense machineries, which are endogenous antioxidants, to guide against the deleterious 64 effect of these reactive oxygen species [11]. However, during oxidative stress these 65 66 endogenous antioxidants get unbalanced by exogenous and endogenous factors leading to 67 various disease conditions [12]. The excessive production of oxidants have led to increased 68 investigations to identify potential antioxidants from natural products basically from plants [13]. The harmful effects of oxidative stress can be reduced by a constant supply of natural 69 products [14]. It is has been well established that herbal medicines are a safer option for 70 71 prevention of diseases mediated by oxidative stress [15].

This investigation focuses on evaluating the scavenging activities and antioxidant properties of three different species of Nigeria soybeans.

#### 75 2. Materials and Methods

# 7677 2.1 Collection and Extraction of Plant Materials

78

74

Three accessions *TGx-1835-10E*, *TGx-1987-62F* and *TGx* 1951-3F of soybean were collected at National cereals research institute, Niger state, Nigeria. The accessions were oven dried at 40 °C for 48 hours to get rid of absorbed moisture and the dry seeds were reduced to fine powder using an electronic blender. Fifty (50) gram of powdered material were subjected to soxhlet extraction using 80% methanol.

84 85

### 2.2 Determination of Total Phenol Content`

86

87 The method of Singleton and Rossi [16] was used as described by Gulcin et al [17] using the Folin ciocalteu's phenol reagent which is an oxidizing reagent. To a mixture of 0.1 ml of 88 89 sample and 0.9 ml of distilled water, was added 0.2 ml of Folin-ciocalteu's phenol reagent 90 and the resulting mixture vortexed. After 5 minutes, 1.0 ml of 7% (w/w) Na<sub>2</sub>CO<sub>3</sub> solution then 91 added and the solution was then make up to 2.5 ml before incubating for 90 minutes at room temperature. The absorbance against a negative control containing 0.1ml of water in place 92 93 of the sample was then taken at 750 nm. Gallic acid (0.1mg/ml) was used as standard in 94 order to determine Gallic acid Equivalent (GAE) of sample, after preparing a calibration 95 curve. Distilled water was used as blank.

96 97

### 2.3 Determination of Total Flavonoid Content

98

99 Standard quercetin with varying concentration 20, 40, 60, 80 and 100 µg/ml were used as 100 standard. The assay was carried out based on the Aluminium chloride colorimetric assay 101 method according to Zhilen [18] as described by Miliauskas [19]. To 0.1 ml of 102 extract/standard was added 0.4ml of distilled water. This was followed by 0.1ml of 5% 103 sodium nitrite. After 5minutes, 0.1ml of 10% Aluminum Chloride and 0.2ml of sodium 104 hydroxide was added and the volume was made up to 2.5ml with distilled water. The 105 absorbance at 510nm was measured against the blank. The total flavonoid content of the 106 plant, expressed as mg quercetin equivalents per gram of the plant extract is calculated as:

- 108 X = Total content of flavonoid compound in quercetin equivalent
- 109 q= concentration of quercetin established from the standard curve
- 110 V= volume of extract (ml)
- 111 w= weight of the crude methanolic extract obtained.

# 112 113 2.4 2, 2-Diphenyl-2-Picryl-Hydrazyl Radical Scavenging Assay

The radical scavenging ability of the samples was determined using the stable radical DPPH (2, 2-diphenyl-2-picryl-hydrazyl hydrate) as described by Brand-Williams [20]. To 1 ml of different concentrations (5, 2.5, 1.25, 0.625, 0.3125 and 0.15625 mg/ml) of the extract or standard in a test tube was added 1 ml of 0.3 mM DPPH in methanol. The mixture was mixed and incubated in the dark for 30 minutes after which the absorbance was read at 517 nm against a DPPH control containing only 1 ml methanol in place of the extract.

120

121 The percent of inhibition was calculated as follows:

122 I% = [(Ablank-Asample)/Ablank] x 100

Where  $A_{blank}$  is the absorbance of the control (containing all reagents except the test compound), and  $A_{sample}$  is the absorbance of the test compound. Sample concentration providing 50% inhibition (IC<sub>50</sub>) was calculated from the graph plotting inhibition percentage against extract concentration.

# 127128 2.5 Inhibition of Nitric Oxide (NO) Radical

129

#### 130 The nitric oxide scavenging activity of the sample was measured spectrophotometrically 131 according to the method of Green [21] as described by Marcocci et al. [22]. The reaction 132 mixture, containing 0.1 ml of different concentrations (10, 5, 2.5, 1.25, 0.625, 0.3125 mg/ml) 133 of the oil extract and 0.9 ml of sodium nitroprusside (2.5 mM) in phosphate buffer saline 134 (pH 7.2, 10 mM) was incubated under illumination for 150 min. After incubation, 0.5 ml of 1% 135 sulphanilamide in 5% phosphoric acid was added and incubated in the dark for 10 min., 136 followed by addition of 0.5 ml 0.1% NED (N-1-napthylethylenediamine dihydrochloride). The 137 absorbance of the chromophore formed was measured at 546nm [23]. The percentage 138 inhibition of nitric oxide radical formation was calculated as expressed above in DPPH 139 radical scavenging assay.

140

#### 1412.6Determination of Total Antioxidant Capacity

142 This method is based on the reduction of Molybdenum (VI) to Molybdenum (V) by the extract 143 144 and the subsequent formation of a green phosphate/Molybdenum (V) complex at an acidic 145 pH [9]. To 0.1 ml of the extracts (1 mg/ml) or standard solutions of ascorbic acid (20, 40, 146 60, 80, 100 µg/ml) was added 1 ml of the reagent solution which consisted of 0.6 M 147 sulphuric acid, 28 mM sodium phosphate and 4 mM ammonium molybdate. The tubes 148 containing the reacting mixture were incubated in a water bath at 95°C for 90 min. The 149 mixture was then allowed to stand and cool to room temperature and the absorbance 150 measured at 695nm against a blank which consisted of the reacting mixture containing 151 distilled water in place of the extract. The antioxidant activities of the extracts were 152 expressed as an ascorbic acid equivalent.

153

### 1542.7Ferric Reducing Antioxidant Power (FRAP)

155

The FRAP working reagent consisted of 300 mM acetate buffer (pH 3.6), 10 mM 2, 4, 6-tri-(2-pyridyl)-1, 3, 5-triazine and 20 mM FeCl<sub>3</sub>.6H<sub>2</sub>O were mixed together in the ratio of 10:1:1 respectively. A 50  $\mu$ l aliquot of the oil extract at 0.1 mg/ml and 50  $\mu$ l of standard solutions of ascorbic acid (20, 40, 60, 80, 100  $\mu$ g/ml) were added to 1 ml of FRAP reagent in duplicate tubes. Absorbance measurement was taken at 593nm exactly 10 mins after mixing against reagent blank containing 50  $\mu$ l of distilled water. All measurements were taken at room temperature with samples protected from direct sunlight. The Ferric reducing antioxidant power was expressed in ascorbic acid equivalent concentration (EC) which was defined as the concentration of antioxidant that gave a ferric reducing ability equivalent to that of the ascorbic acid standard [24].

166 167

### 2.8 Ferrous Ion-chelating Ability Assay

168

169 The ferrous ion-chelating (FIC) assay was carried out according to the method of Singh and 170 Rajini [25] with some modifications. Solutions of 2 mM FeCl<sub>2</sub>·4H<sub>2</sub>O and 5 mM ferrozine were 171 diluted 20 times. Briefly, an aliquot (1 ml) of different concentrations of extracts were mixed 172 with 1ml FeCl<sub>2</sub>·4H<sub>2</sub>O. After 5 min incubation, the reaction was initiated by the addition of 173 ferrozine (1 ml). The mixture was shaken vigorously and after a further 10 min incubation 174 period the absorbance of the solution was measured spectrophotometrically at 562 nm. The percentage inhibition of ferrozine-Fe<sup>2+</sup> complex formations was calculated by using the 175 176 formula:

177

181

178 Chelating effect % =  $[(A_{control}-A_{sample})/A_{control}] \times 100$ 

179 Where, A<sub>control</sub> = absorbance of control sample (the control contains FeCl2 and

180 ferrozine, complex formation molecules) and  $A_{sample}$  = absorbance of a tested samples.

### 182 2.9 CUPRAC Assay

183 In order to determine the cupric ions (Cu<sup>2+</sup>) reducing ability of extracts, the method of Apak 184 [26]. was used with little modification as described by Gulcin [27]. Briefly, 0.25 ml CuCl<sub>2</sub> 185 solution (0.01M), 0.25 ml ethanolic neocuproine solution (7.5 \* 10-3M), and 0.25ml 186 CH<sub>3</sub>COOH<sub>4</sub> buffer (1M) were added to a test tube, followed by mixing with 0.25ml of extracts. 187 188 The total reaction volume was adjusted to 2 ml with distilled water, and the solution was 189 mixed well. The tubes were stoppered and kept at room temperature for 30 min, and 190 absorbance was measured at 450 nm. Increased absorbance indicates increased reduction 191 capability which is express as trolox equivalent (TEAC) using trolox as standard. 192

### 193 3. Statistical and Data Analysis

194

All data obtained from the various experiment were subjected to descriptive statistical calculation using GraphPad® Instat Statistical Package and expressed as mean values and standard error of mean (S.E.M) of multiple measurements (usually n=3). The IC<sub>50</sub>, values were estimated from graphical linear plots. The level of significance was chosen as p<0.05. All the graphs were plotted using GraphPad ® Prism 5 Graphical package. The correlation coefficient, slope and intercept were obtained by linear regression analysis.

201

### 4. RESULT AND DISCUSSION

202 203

204 Table 1 showed the results of the DPPH inhibitory assays carried out on the three 205 accessions TGx-1835-10E, TGx-1987-62F and TGx 1951-3F of soybean TGx 1951-3F has 206 the highest DPPH radical scavenging activity with IC<sub>50</sub> values of 2.61±0.02 mg/ml, compared 207 to TGx-1835-10E and TGx-1987-62F with an IC<sub>50</sub> of 2.80  $\pm$  0.06 and 3.28  $\pm$  0.05 mg/ml 208 respectively. The radical scavenging activity soybeans exhibit a dose dose/concentration 209 dependent relationship. DPPH has been used to evaluate the free radical- scavenging 210 activity of natural antioxidants. DPPH is a radical that changes into a stable compound by 211 reacting with an antioxidant and the extent of the reaction depends on the hydrogen donating ability of the antioxidant [28]. The ability of soybean accession to scavenge DPPH 212 213 radicals suggests that it is an electron donor which can react with free radicals to convert 214 them to more stable products and thereby terminate radical chain reactions.

216 The nitric oxide inhibition assay also showed that TGx 1951-3F has the highest activity with 217  $IC_{50}$  value of 2.58 ± 0.02 mg/ml, compared to TGx-1835-10E and TGx-1987-62F with an  $IC_{50}$ 218 of 3.77 ± 0.06 and 3.12 ± 0.10 mg/ml respectively as shown in Table 2. Nitric oxide is an 219 important chemical mediator produced by several different types of cells, including endothelial cells, neurons and macrophages. They are involved in the regulation of various 220 221 physiological processes, for example the early release of nitric oxide through the activity of 222 constitutive nitric-oxide synthase is important in maintaining the dilation of blood vessels. 223 However excess concentration of NO is associated with several oxidative damages 224 (diseases), for example excess NO reacts with oxygen and superoxide radical, forming the 225 highly reactive peroxynitrite anion (ONOO-) [29]. In this study, the extract inhibits nitrite 226 formation by directly competing with oxygen in the reaction with nitric oxide, thereby inhibiting the formation of anions. The result shows that the soybean has moderate nitric 227 228 oxide scavenging activity compared to the standard ascorbic acid.

229

230 In the Ferrous Ion-chelating Ability (FIC) assay, the result in Table 3 shows that the TGx 231 1951-3F show the highest FIC activity with the least IC<sub>50</sub> value of 1.38  $\pm$  0.07 mg/ml, 232 compared to TGx-1835-10E and TGx-1987-62F with an IC<sub>50</sub> of  $1.86 \pm 0.16$  and  $2.07 \pm 0.16$ mg/ml. In metal chelating assay, TGx 1951-3F has the higher ability to chelate metals 233 234 followed by TGx-1835-10E and TGx-1987-62F. Free iron plays an important role in formation of reactive oxygen species [30]. In addition, excessive iron deposition in different vital 235 236 organs can lead to the loss of function of those organs like liver, kidney etc. So, chelation of 237 this free iron can prevent the formation of free-radicals as well as can prevent the damage of this vital organ. Ferrozine in complex with ferrous ion (Fe<sup>2+</sup>) produces a violet colour. In the 238 239 presence of a chelating agent, complex formation is interrupted by competing with ferrozine in chelating Fe<sup>2+</sup> and as a result the violet color of the complex is decreased. In this study, 240 the results demonstrated that formation of the ferrozine-Fe<sup>2+</sup> complex is interrupted in the 241 242 presence of the soybean accession and standard EDTA.

The ability of the accessions to act as reducing agent was also evaluated using FRAP, TAC and CUPRAC assays. The results show that TGx 1951-3F has highest reducing property follow by TGx-1835-10E and TGx-1987-62F in terms of ascorbic acid equivalent (AAE) of the three samples Table 4. This same trend was also observe in antioxidant constituent present in the samples as TGx-1835-10E has higher phenolic and flavonoid content compared to TGx-1835-10E and TGx-1987-62F as shown in Table 5.

273 

282 Plant phenolics are known to exhibit potent antioxidant activity [31]. Also, the anti-oxidative 283 properties of flavonoids are due to several different mechanisms, such as scavenging of free 284 radicals, chelation of metal ions, and inhibition of enzymes responsible for free radical 285 generation [32]. Hence, the observed antioxidant activity of the extracts of soybean accession may be due to the presence of these constituents. However, variations in activity 286 of different accessions may be due to the diversity in the basic chemical structure of phyto-287 constituents, which make them, possesses different degree of antioxidant activity against 288 289 different free radicals.

290 291

#### 292 **5. CONCLUSION**

The result of this study revealed that the three accessions TGx-1835-10E, TGx-1987-62F and TGx 1951-3F of soybean, contains huge amounts of flavonoids and phenolic compounds, exhibits high antioxidant and free radical scavenging activities. This important evident suggests that the three accessions have great health benefit.
