

2 **Transfer and Accumulation of some heavy metals in**  
3 **native vegetation plants**

4  
5 **ABSTRACT**

6 **Phytoremediation is the use of selected plants in order to eliminate some heavy**  
7 **metals from soil, or wastewater in a cost-effective method. This study aimed to**  
8 **investigate the concentrations of heavy metals such Cd, Pb, Cu, Zn and Cr in soils**  
9 **and vegetation plants grown in Wadi Hanifa, Riyadh city, Kingdom of Saudi**  
10 **Arabia. Five sites have been chosen for collected plant samples (shoot and root)**  
11 **for one year, and five plant species have chosen which distributed in the study**  
12 **area including: *Ziziphus spina-christi*, *Prosopis juliflora*, *Rhazya stricta*,**  
13 ***Ochradenus baccatus* and *Conocarpus erectus*. Determination of Cd, Pb, Cu, Zn**  
14 **and Cr has been done with ICP. Accumulation coefficient (AC), and translocation**  
15 **factor (TF) have been calculated to evaluate the ability of selected plants to extract**  
16 **the heavy metals from soil. The results indicated that *Ziziphus spina-christi* and**  
17 ***Conocarpus erectus* shows the high ability for accumulate the Pb and Zn in its**  
18 **root and shoot compare with other plants. The trend of heavy metal transfer**  
19 **factors for different plants was in the order of Cd > Cr > Pb > Cu > Zn. The**  
20 **accumulation coefficient (AC) of the Cd, Pb, Zn, Cu and Cr in the roots/soil of**  
21 ***Ziziphus spina-christi*, *Prosopis juliflora*, *Rhazya stricta*, *Ochradenus baccatus***  
22 **and *Conocarpus erectus* were varied from 0.80 to 3.60. The order of AC in the**  
23 **shoot as follows: Pb>Cu>Zn>Cr>Cd, while in roots of as follows: Cd>Cr>Pb>Cr>**  
24 **Zn.**

25 *Key words: Heavy metals, transfer, accumulation, Ziziphus spina-christi, Prosopis juliflora,*  
26 *Rhazya stricta, Ochradenus baccatus and Conocarpus erectus.*

27  
28 **1. INTRODUCTION**

29 Heavy metals are becoming increasingly prevalent in soil environments as a result of  
30 wastewater irrigation, sludge application, solid waste disposal, automobiles exhaust and  
31 industrial wastewater discharge [1, 2]. The release of heavy metals into the environment

32 by industrial activities presents a serious environmental threat. Heavy metal  
33 contamination is considered as a dominant source of pollution and a potentially growing  
34 environmental and human health concern worldwide [3, 4]. Copper, Pb and Cd can  
35 become a sanitary and ecological threat to drinking water resources, even at very low  
36 concentrations [5]. In addition, Cd and Zn are common industrial pollutants [6, 7]. Both  
37 Cd and Zn are harmful to plant at relatively low concentrations [8]. Plant uptake of some  
38 heavy metals from soil occurs either passively with the mass flow of water into the roots,  
39 or through active transport crosses the plasma membrane of root epidermal cells [8].

40 Some kind of plants can potentially accumulate certain heavy metal ions an order  
41 of magnitude greater than the surrounding medium [9]. Therefore, clean alternatives  
42 must be developed in order to remove heavy metals from effluents. Heavy metals can be  
43 removed from industrial wastewater and contained soil by a range of physico-chemical  
44 remediation technologies such as precipitation, ion exchange, adsorption,  
45 electrochemical processes and membrane processes [10-12]. However, these  
46 technologies are expensive and energy-intensive, driving towards a search of cheaper  
47 alternatives [13].

48 Phytoremediation is a method of environmental treatment that makes use of the  
49 ability of some plant species to accumulate certain heavy metals in amounts exceeding  
50 the nutrients requirements of plants. Phytoextraction is one of the elements of  
51 phytoremediation in which heavy metals from the contaminated site are taken up by  
52 plants and then transported from roots to shoots and removed with crops from a  
53 specified area of nature [14]. Phytoremediation is phytostablization where plants are  
54 used to minimize some of heavy metals mobility in contaminated soils. Nowadays, than  
55 500 plants are known as hyper accumulation of heavy metals into their aboveground  
56 biomass including weeds, trees, grasses and vegetable crops [15, 16].

57 The objectives of this research were to determine the concentration of some heavy  
58 metals in some native plant species growing on a contaminated soil which located in the  
59 Wadi Hanifa, Riyadh city, Kingdom of Saudi Arabia and to assessment and evaluation of  
60 heavy metals pollution.

61

## 62 **2. Materials and Methods**

## 63 **2.1 Experimental sit description and soil chemical analysis**

64 Wadi Hanifa (24°14'27.0"N 47°00'00.0"E) is a valley in the Najd region, Riyadh province,  
65 in central Saudi Arabia. The valley runs for a length of 120 km from northwest to  
66 southeast, cutting through the city of Riyadh, the capital of Saudi Arabia. Temperatures  
67 in summer reach an average of 43.9 °C and precipitation averages only 62 mm per year  
68 in the driest places. Rain falls with great intensity for short periods, causing flash floods.  
69 The nature of the dry, warm climate leads to a high percentage of the scarce rainfall  
70 being instantly evaporated [17, 18]. Represented soil samples were collected from the  
71 surface layer (0-20 cm depth) by 20x20 m. The soil samples were air-dried at room  
72 temperature for two weeks and then sieved by 2-mm stainless steel sieve. The pH and  
73 EC of samples were measured (using 1:5 ratio of w/v with demonized distilled water) by  
74 pH-meter and the electrical conductivity (EC) meter respectively. Complex metric EDTA  
75 titration was employed for determining Ca<sup>++</sup> and Mg<sup>++</sup> simultaneously and individually  
76 [19]. Sodium and potassium was determined using flame photometer (Corning 400).  
77 Carbonate and bicarbonate were determined by titration with H<sub>2</sub>SO<sub>4</sub> while silver nitrate  
78 was used to determine chloride [19]. Sulphate was determined by turbidity method as  
79 described by [20]. Particle size distribution was analyzed according to [21]. Calcium  
80 Carbonate content was determined using the Calcimeter [22]. Some selected soil  
81 physical and chemical properties are presented in Table (1). The total content of heavy  
82 metals (Cd, Pb, Zn, Cu, Cr and Zn) in the soil samples were determined after digestion  
83 with HNO<sub>3</sub>-HClO<sub>4</sub>-HF as described by Hossner [23], then total heavy metals content  
84 were determined using ICP (Perkin Elmer, Model 4300DV).

85

## 86 **2.2 Plant sample collection and plant analysis**

87 Five plant native plant species (*Ziziphus spina-christi*, *Prosopis juliflora*, *Rhazya stricta*,  
88 *Ochradenus baccatus* and *Conocarpus erectus*) based on their coverage at the Wady  
89 Henifia, Riyadh city, Saudi Arabia were collected in acid-washed polyethylene bags  
90 according to the sampling procedures of Australian National Botanic Garden [23, 24].  
91 Table 2 shows the botanical and vernacular names of plants species collected from the  
92 study area. The collected plant samples separated into shoot and root, washed gently  
93 with demonized water for approximately 5 minutes to remove soil particles adhered to  
94 the plant roots, then, air-dried at 60° and finally ground to powder using a Wiley mill. The

95 plant samples were acid digested with HNO<sub>3</sub>-HClO<sub>4</sub> mixture according to Chapman and  
96 Pratt, (1996). After digestion, the cooled samples was diluted to 50 mL with distilled  
97 water and filtered into plastic bottles pre washed with acid. The concentrations of heavy  
98 metals mainly (Cd, Pb, Zn, Cu, Cr and Fe) were measured using ICP (Perkin Elmer,  
99 Model 4300DV). Reagent blanks and standards were used where appropriate to ensure  
100 accuracy and precision in heavy metals analysis.

101

## 102 **2.3 Estimation heavy metals between soil and plant**

### 103 **2.3.1 Accumulation coefficient**

104 Accumulation coefficient was used for evaluation of heavy metals accumulation in the  
105 plant according to [25] as flows:

$$106 \quad Ac = \frac{C_{\text{root, stem, leaves}}}{C_{\text{soil}}}$$

107 Ac= concentration of heavy metal in plant shoot (mg kg<sup>-1</sup>)/ concentration of heavy metal  
108 in background soil (mg kg<sup>-1</sup>).

### 109 **2.3.2 Translocation factor**

110 Transfer factor (TF) describes the amount of heavy metal transferred from the soil to the  
111 plant under equilibrium conditions [26]. Heavy metals from the soil are consumed by  
112 plant roots and then distributed in various plant tissues. Transfer of this heavy metal  
113 from soil to plant tissues is measured using the TF indicator, which measures the ratio of  
114 the concentration of a specific metal in plant tissue to the concentration of the same  
115 metal in soil. If the TF values are ≥ 1.0 it shows a higher uptake of metal from soil by the  
116 plant, while lower values mean less absorption of the metal from the soil, and the plant  
117 can be used for consumption [27].

118 Translocation Factor (TF) was calculated as follows:

119

$$TF = \frac{\text{Metal}_{shoot}}{\text{Metal}_{roots}}$$

120

### 121 3. RESULTS AND DISCUSSION

#### 122 3.1 Soil characteristics

123 Selected physical and chemical properties of soil collected from the Wadi Hanifa are  
124 listed in Table 1. The soil texture was sandy; the soil pH was 7.80 with EC 4.50 dS m<sup>-1</sup>  
125 1in. In addition, results indicated that the percentage of CaCO<sub>3</sub> was 19.2%. Also A wide  
126 range of soil heavy metals concentration was observed of soil at start of the collecting  
127 the plant samples. The total content of Cu 20±0.10 mg kg<sup>-1</sup>; Zn 35±1.20 mg kg<sup>-1</sup>; Pb  
128 15±0.70 mg kg<sup>-1</sup>; Cd 0.20±0.01 mg kg<sup>-1</sup> and Cr 30±1.15 mg kg<sup>-1</sup>. According to Lindsay,  
129 [28] who reported that, 35 mg kg<sup>-1</sup> Zn 40 mg kg<sup>-1</sup> Pb, 10 mg kg<sup>-1</sup> Cd, 0.05 mg kg<sup>-1</sup> and Cr  
130 95 mg kg<sup>-1</sup> the average of heavy metals concentrations in common soils. The results  
131 indicated that, the total concentration of Cr, Pb, Zn and Cu within the normal range of  
132 common soils expect the Cd. Wastewater samples were collected from different  
133 locations in the Wadi Hanifa. The results indicated that the water quality is characterized  
134 by high pH and contains high concentrations of Fe, Mn, Zn, Cd, Ni, Pb, and Mo  
135 compared with Kingdom of Saudi Arabia [6].

136

#### 137 3.2 Concentration of heavy metal in plant species

138 Table 3 show the heavy metals content in shoot and roots of selected plant species. In  
139 general, the concentration of Cd, Pb, Zn, Cu and Cr in roots of *Ziziphus spina-christi*,  
140 *prosopis juliflora*, *Rhazya stricta*, *Ochradenus baccatus* and *Conocarpus erectus* plant  
141 species was higher than that in shoots. Concentration of heavy metals by shoots and  
142 roots varied with heavy metals type and plant species. Plant *Ziziphus spina-christi* and  
143 *Conocarpus erectus* shows the high ability for accumulate the Pb and Zn in its root and  
144 shoot compare with other plants. All the studied plant species showed ability to  
145 accumulate the Pb, Zn, Cu, Cr expect Cd. The results in agreement with reported by [29,  
146 30]. Some of heavy metal from soil occurs either passively with the mass flow of water

147 and accumulated plant roots [9, 31]. Some of plants can accumulate certain metal ions  
148 in higher concentration than the surrounding soil [32]. On the study of heavy metals  
149 accumulation on second industrial wastewater of Riyadh city, [7] founded that  
150 concentrations of Cr, Ni, Cu, Zn, and Pb in *Fagonia indica* and *Cenchrus ciliaris* plants  
151 were markedly higher than in *Rhazya stricta* plant. According to State Environmental  
152 Protection Administration and China, the average concentration of Cr, Ni, Cu and Cd  
153 elements were 0.50, 9.0, 20 and 0.20 mg kg<sup>-1</sup> on a dry weight basis, respectively. In the  
154 current study, the concentration of Cr, Ni and Zn concentrations in roots and shoot of  
155 *Ziziphus spina-christi*, *Prosopis juliflora*, *Rhazya stricta*, *Ochradenus baccatus* and  
156 *Conocarpus erectus* were exceeded the concentration limits. The heavy metals enter the  
157 environment from both natural processes which included weathering, parent material  
158 rock erosions and atmospheric deposition and from anthropogenic activities such as  
159 using chemicals, sewage sludge disposal, mining [33-35]. The heavy metal accumulated  
160 would be contaminated the soil and vegetables at high concentrations.

### 161 **3.2 Accumulation coefficient (AC)**

162 The accumulation coefficient (AC) of the Cd, Pb, Zn, Cu and Cr in the roots/soil of  
163 *Ziziphus spina-christi*, *prosopis juliflora*, *Rhazya stricta*, *Ochradenus baccatus* and  
164 *Conocarpus erectus* were varied from 0.80 to 3.60 (Table 4). The results indicated that  
165 the AC values depend on the heavy metal type and plant species. Regardless the AC  
166 values were 0.02-4.0, 0.02-3.40, 0.70-3.60, 0.71-3.90 and 0.46-5.60 for *Ziziphus spina-*  
167 *christi*, *Prosopis juliflora*, *Rhazya stricta*, *Ochradenus baccatus* and *Conocarpus erectus*,  
168 respectively. The order of AC in the shoot as follows: Pb>Cu>Zn>Cr>Cd, while in roots  
169 of as follows: Cd>Cr>Pb>Cr> Zn. The calculated AC values of the heavy metals, in the  
170 roots of *Fagonia indica* and *Cenchrus ciliaris* were 0.31-2.30 [2, 36]. The higher AC  
171 values of studied plant in this study indicated that, these plant species could be  
172 accumulated heavy metals and also are suitable for heavy metal phytoextraction from  
173 contaminated soil.

### 174 **3.2 Transfer Factor (TF)**

175 The calculated (TF) values of transfer the heavy metals from soil to different plant spices  
176 are presented in (Table 5). The TF values varied among the plant species and highest  
177 TF for Cd in *Prosopis juliflora*, *Ochradenus baccatus* flowed by Cr in *Rhazya stricta*,  
178 *Ochradenus baccatus* and and *prosopis juliflora* plant, while the lowest TF for Zn and Cu

179 was recorded in all studied plants. The high TF for Cd, Cr and Pb heavy metals from soil  
180 to plant indicated that a strong accumulation of those metals. The calculated TF values  
181 for heavy metals were found in the order: Cd>Cr>Pb>Zn>Cu. The results indicated that  
182 the plant species have a different ability to accumulate the heavy metals. The results  
183 shows clearly that the plant species differ to use its ability to accumulate the heavy from  
184 the soil (Figure 1). For example, the ability of the *Ochradenus baccatus* and *prosopis*  
185 *juliflora* plant for accumulation of Cd was higher than other plant species, while *Rhazya*  
186 *stricta* have ability to accumulate Cr. The higher the value of TF means that, the more  
187 heavy metal can be accumulated by plants parts. Cadmium, Cr and Pb is the highest TF  
188 values, which agrees with Yang et al., [37]. By comparing TF values, for *Ziziphus spina-*  
189 *christi*, *Prosopis juliflora*, *Rhazya stricta*, *Ochradenus baccatus* and *Conocarpus erectus*  
190 it could be compare the ability of these plant species for accumulation of heavy metals  
191 from the contaminated soil and translocations them in the plant canopy. Plants showing  
192 TF values less than one are unsuitable for photo extraction of some heavy metals  
193 [38]and but can be used as an indicator for soil contamination with some heavy metals.

194

#### 195 **4. CONCLUSION**

196 This study was conducted to screen *Ziziphus spina-christi*, *Prosopis juliflora*, *Rhazya*  
197 *stricta*, *Ochradenus baccatus* and *Conocarpus erectus* plant species growing on Wadi  
198 Hanifa, Riyadh city, Kingdom of Saudi Arabia for their potential for removal of some  
199 heavy metal. The study confirmed that there were differences in the heavy element  
200 contents in plant species. The results showed that the existence Cd, Pb and Cr in the  
201 shoot and roots of *Prosopis juliflora*, *Ochradenus baccatus* and *Prosopis juliflora* plant  
202 species. The current study shows clearly that the plant species differ to use its ability to  
203 accumulate the heavy from the soil and wastewater and the recommendation that those  
204 species, with high concentration in heavy elements.
