

1 **Microorganisms Isolated from Hospital**
2 **Environmental Surfaces in Akure Metropolis, Ondo**
3 **State, Nigeria.**

4
5 **ABSTRACT**

6 Microorganisms Isolated from Hospital Environmental Surfaces in Akure Metropolis, Ondo
7 State, Nigeria were investigated. The study revealed that bacteria were the most predominant
8 microorganisms found in the hospital environmental surfaces than fungi. *Staphylococcus*
9 *aureus*, *Streptococcus pyogenes*, *Escherichia coli*, *Pseudomonas aeruginosa*,
10 *Klebsiellapneumoniae* and *Bacillus cereus* were the bacterial isolates while fungi include
11 *Aspergillus fumigatus*, *Aspergillus niger* and *Candida albicans*. *Staphylococcus aureus* was
12 found to be predominant bacteria but *Aspergillus funmigatus* was the predominant fungi. The
13 result showed that the microbial loads of the public hospitals were higher than that of the
14 private hospitals. The bacteria load of the male ward was found to be higher than that of the
15 female ward while the fungal loads of each of the hospital environmental surfaces of female
16 were higher than that of the male. The study revealed that bacteria were the most
17 predominant microorganisms found in the hospital environment than fungi. *Staphylococcus*
18 *aureus*, *Streptococcus pyogenes*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Klebsiella*
19 *pneumoniae* and *Bacillus cereus* were the bacterial isolates while fungi include *Aspergillu*
20 *sfumigatus*, *Aspergillu sniger* and *Candida albicans*. *Staphylococcus aureus* was found to be
21 predominant bacteria. All the hospital environmental surfaces were contaminated with one or
22 more microorganisms in the course of the research.

23 Keywords: Hospital; ward; environmental; bacteria; fungi.

24 **Introduction**

25 Nosocomial infection is an infection occurring in a patient in a hospital or other health care
26 facility in whom the infection was not present or incubating at the time of admission. It is
27 estimated that in developing countries, nosocomial infections concern above 25% of
28 hospitalized patients, and in the developed countries from 5 to 10% (Wenzel, 1999). This
29 includes infections acquired in the hospital but appearing after discharge, and also
30 occupational infections among staff of the facility (Benenson, 1995). The sources of

31 infections can be: patients, medical personnel, visitors or parts of the environment: equipment
32 and hospital items, also arthropods inhabiting hospitals.

33 Patient care is provided in facilities which range from highly equipped clinics and
34 technologically advanced university hospitals to front-line units with only basic facilities
35 (World Health Organization, 2002). Despite progress in public health and hospital care,
36 infections continue to develop in hospitalized patients, and may also affect hospital staff.
37 Many factors promote infection among hospitalized patients: decreased immunity among
38 patients; the increasing variety of medical procedures and invasive techniques creating
39 potential routes of infection; and the transmission of drug-resistant bacteria among crowded
40 hospital populations, where poor infection control practices may facilitate transmission
41 (World Health Organization, 2002).

42 Hospital acquired infection is an additional affliction to the patient admitted to the hospital
43 for some serious illness and is caused by pathogens which are prevalent in hospital
44 environment (Davaneet *al.*, 2014). In the hospital, microbes are ubiquitous; and can reach
45 the sick patient through various sources, such as air, water, food, contaminated equipments,
46 linen, catheters, scopes, ventilators, contaminated disinfectants and other preparations used
47 for treatment, visitors, infected patients, etc (Davaneet *al.*, 2014). Recently, the probable
48 involvement of surfaces and equipment from the hospital environment as a disseminating
49 source of pathogens, including resistant bacteria, has been highlighted (Schulsteret *al.*, 2003).
50 There are no meaningful standards for permissible levels of microbial contamination of
51 inanimate surfaces in hospital environment, but an increased microbial load on surfaces may
52 imply the possibility of finding a pathogen (Dancer, 2004). Microorganisms that are often
53 associated with hospital acquired infections are *Staphylococcus aureus*, *Micrococcus* sp.,
54 *Pseudomonas* sp., *Proteus* sp., *Escherichia coli*, *Enterobacter*, *Bacillus cereus*, *Cladosporium*
55 sp., *Aspergillus* sp., and viruses (Ekhaiseet *al.*, 2008). *Pseudomonas aeruginosa* has been
56 particularly incriminated in nosocomial infection because of its intrinsic resistance to most
57 antibiotics and its ability to survive and multiply at low temperatures and in disinfectant
58 solutions (Ohsakiet *al.*, 2007).

61

62 MATERIALS AND METHODS

63 Description of study location

64 This research work was carried out from September 2016 to April, 2017 in Akure metropolis,
65 Ondo state, Nigeria. Akure covers an area of 14,798.8 ,993.7 square kilometers and lies at
66 latitude 7°15'0"N, 7° 11' N 5°11'42"E and longitude 5°11'42"E, 5°35'E. Akure is one of the
67 18 local government areas of Ondo State with a population of 484,798 based on the 2006
68 population census. It is situated in the peripheral zone of the rainforest of Ondo state. Akure
69 is the administrative capital of Ondo state. Akure lies about 70°15' north of the equator and
70 50°15' east of the Meridian. It is about 700 km Southwest of Abuja and 311 km north
71 of Lagos State. The town is situated in the tropic rainforest zone in Nigeria.

72 Collection of samples

73 Samples were collected by swab sticks from Male Accident and Emergency Bed, Female
74 Accident and Emergency Bed, Male Toilet, Female Toilet, Male Surgical Ward Chair,
75 Female Surgical Ward Chair, Male Medical Ward Floor, Female Medical Ward Floor, Male
76 Ward Air flora, Female Ward Air flora, Theatre Couch, Injection Room Tables, Neonatal
77 Ward Couch and Maternity Ward Couch from Health Centre FUTA, Don Bosco Catholic
78 Hospital and State Specialist Hospital Akure. The date, time, conditions and sites of sampling
79 were noted. Basically, swabs were used, at least, for each sampling site. For sampling, swabs
80 were moistened in 2 ml sterile saline solution and rolled several times over a surface area of
81 around 25 cm², and the swab sticks were transported to the laboratory. Sampling was always
82 done between 8-10am

83 Isolation of microorganisms from hospital environment

84 Isolation of microorganisms from hospital environment were carried out as described
85 by Bakkaliet *al.* (2005) with slight modification. Basically, swabs were used, at least, for
86 each sampling site. For sampling, swabs were moistened in 2 ml sterile saline solution and
87 rolled several times over a surface area of around 25 cm², and the swab sticks were
88 transported to the laboratory. Sampling was always done between 8-10am. A five-fold serial
89 dilution was made and 0.1 ml of the 10⁻³ and 10⁻⁵ dilutions were uniformly pour-plated onto
90 14 cm diameter wide agar plates and of nutrient agar, Potato dextrose agar, MacConkey agar
91 and EMB agar.

92

93 **Characterization of bacterial isolates**

94 The pure culture of each isolate was examined. Microscopic examination, staining
95 techniques and biochemical tests were carried out on the isolates according to the methods
96 described by Olutiola *et al.* (2000) and Cheesbrough (2010).

97 **Identification of fungal isolates**

98 Fungal isolates were characterized and identified based on macroscopic and
99 microscopic details with reference to Barnett and Hunter (1998).

100 **Statistical analysis of data**

101 All experiments were carried out in triplicate, and data obtained were subjected to one way
102 analysis of variance, while the means were compared by Duncan's New Multiple Range Test
103 at 95 % confidence interval using Statistical Package for Social Sciences version 16.0.
104 Differences were considered significant at $p \leq 0.05$.

105 **RESULTS**

126 Table 2: The fungal load of each of the fungi isolated from different hospital environmental
 127 surfaces are shown in Table 2, it was observed that fungal load of the toilet was found to be
 128 higher than other surfaces, while the fungal load isolated from each of the female hospital
 129 environmental surfaces was higher than that of the male hospital environmental surfaces. It
 130 was also observed that the fungal loads isolated from government own hospital was higher
 131 than those microorganisms isolated from private hospital

132 **Table 3: Rate of occurrence of different bacteria isolated from FUTA Health**
 133 **Centre, State Specialist hospital Akure and Don Bosco Hospital Akure**

Bacteria	Number of surfaces Tested	Percentage positivity (%)
<i>Staphylococcus aureus</i>	39	22.81
<i>Streptococcus pyogenes</i>	24	14.04
<i>Escherichia coli</i>	21	12.28
<i>Pseudomonas aeruginosa</i>	27	15.79
<i>Klebsiella pneumonia</i>	33	19.30
<i>Bacillus cereus</i>	27	15.79
Total	171	100.01

134 Table 3: The rate of occurrence of different bacteria isolated from different hospital
 135 environmental surfaces is presented in Table 3. It was observed that *Staphylococcus*
 136 *aureus* had the highest rate of occurrence, while *Escherichia coli* had the lowest rate of
 137 occurrence out of the bacteria isolated for different hospital environment surfaces

138

139

140 **Table 4: Rate of occurrence of different fungi isolated from FUTA Health Centre,**
 141 **State Specialist hospital Akure and Don Bosco Hospital Akure**

Fungi	Number of surfaces Tested	Percentage positivity (%)
<i>Aspergillusfumigatus</i>	21	36.84
<i>Aspergillusflavus</i>	18	31.58
<i>Candida albicans</i>	18	31.58
Total	57	100

142 Table 4: The rate of occurrence of different fungi isolated from different hospital
 143 environmentalsurfaces is presented in Table 4. It was observed that *Aspergillusfumigatus* had
 144 the highest rate of occurrence followed by *Candida albicans* and *Aspergillusniger* which
 145 share the same number percentage positivity.

146 **DISCUSSION**

147 Hospital associated infections have been linked with many factors among which is the
 148 microbial quality of the indoor air of different wards and units of each hospital (Ekhaiseet *al.*,
 149 2010). This type of infection occurs in 5% of all acute care hospitalization in the United State
 150 and has been reported to be responsible for the death of one out of every five thousand
 151 patients attending an American hospital (Putsept, 1981). In Nigeria, the rate of nosocomial
 152 infection ranges between 2.7%-3.8% (Onipedeet *al.*, 2004). This calls for looking at every
 153 possible measure to control the rise including (among other investigations) examining the
 154 quality of indoor air of the hospital wards and units. Each of the hospital environmental
 155 surfaces was contaminated with microorganisms.

156 Bacteria were found to be more predominant than fungi, the bacteria isolated from the
 157 hospital surfaces were *Bacillus cereus*, *Escherichia coli*, *Klebsiella pneumonia*, *Pseudomonas*
 158 *aeruginosa*, *Staphylococcus aureus*, and *Streptococcus pyogenes* while fungi include
 159 *Aspergillus fumigatus*, *Aspergillus niger* and *Candida albicans*. *Staphylococcus aureus* was
 160 found to be predominant bacteria with the occurrence of 22.81%, this correlate with the
 161 report of Awosika *et al.* (2012) who reported *Staphylococcus aureus* as the most frequently
 162 isolated bacterium from hospital surface. *Staphylococcus aureus* as the most frequently
 163 isolated bacterium from hospital surface has been incriminated in various diseases such as
 164 post-operative infections, urinary tract infections, skin infections, respiratory infections and

165 food poisoning (Murray *et al.*, 1995). Proper control measures, such as increase in hygiene,
166 are required to combat infections by *Staphylococcus aureus* in these hospital wards and units
167 (Awosika *et al.*, 2012). The occurrence of bacteria in hospitals has been commonly
168 related to some possible sources of dissemination: bottle soap (Buffet-Bataillon *et al.*,
169 2009), hands of healthcare professionals (Tan *et al.*, 2013), gloves and gowns (Rock *et*
170 *al.*, 2014), mobile phones (Ustun and Cihangiroglu, 2012) paper money and coins
171 (Angelakiset *al.*, 2014). *Aspergillus fumigatus* was found to be predominant fungi with
172 frequency occurrence of 36.84%, this correlate with the report of Cagginao *et al.* (2014) who
173 reported that *Aspergillus fumigates* was the most commonly isolated (68.5%).

174 The bacterial load of the male ward was found to be higher than that of the female,
175 this could be due personal hygiene of the female, this in line with the report of Ekhaise *et al.*
176 (2008) who reported that quantitative study of different hospital units showed that the
177 children ward and female ward had the highest total bacterial count followed by the
178 bacteriology laboratory.

179 The fungal loads of each of the hospital environment surfaces of female were higher
180 than that of the male. In hospital environments, airborne molds are a potential risk for
181 patients because of possible inhalation of conidia (Augustowska and Dutkiewicz , 2006).
182 Because surgical procedures expose patients to infective complications, the operating theater
183 is considered a complex habitat in which all sources of pollution have to be kept under
184 control (Partridge-Hinckley *et al.*, 2009; Grossiet *al.*, 2011). In particular, the widespread
185 presence of *Aspergillus* spp. is the major extrinsic risk factor for invasive aspergillosis,
186 caused by *A. fumigates* and other species of *Aspergillus*, such as *A. flavus*, *A. niger*, and *A.*
187 *terreus*, depending on the local epidemiology (Singh and Paterson, 2005) and according to
188 the season (Panagopoulou *et al.*, 2007).

189 The microbial load of the public hospital were higher than that of the private, this
190 tallied with the report Ekhaise *et al.* (2008) who reported high microbial counts recorded for
191 the public hospital (Central Hospital) as compared to private hospital (Faith Medical
192 Center), could be due to the subsidizes rate of the public hospital so as accommodate
193 more people, compared to the private hospital, where high fees are charged and are not
194 within the reach of the poor people in the society. These findings could be explained by many
195 factors including the number of visitors visiting the children and female wards, which
196 exceeded visitors in other hospital units. It was noted that the amount of materials brought

197 from outside such as personal belongings, food and fruits were more common in children and
198 female wards. These are recognized as sources of hospital contamination. Hospital surfaces
199 are contaminated by factors inherent to the presence of patients, such as biological
200 fluids, sometimes associated to assistance techniques and hygiene. Another
201 contamination factor would be the circulation of vectors as carrier agents for fungi
202 and bacteria resistant to antimicrobials (Prado *et al.*, 2006; Rodovalho *et al.*, 2007)

203 The microbial load of the theater couch and surgical ward were found to be the
204 lowest, this could probably due to the fact that there is high sanitary standards in this area as
205 compared to other hospital areas and also theater is a restricted area, this tallied with
206 submission of Ekhaise *et al.* (2008) who reported that the number of microorganisms in the
207 theater was extremely low.

208 Although, surfaces are not directly connected to transmission in most hospital
209 infections, the impact of hygiene and cleaning procedures in microbial control is
210 evident. It is suggested that microorganisms associated to hospital infections are able
211 to survive during large periods of time, thus being a continuous source of
212 contamination in cases where population control is not efficiently conducted (Kramer
213 *et al.*, 2006; Rossi *et al.*, 2008).

214 Regular surveillance, cleaning and restriction of patients relative might be among the
215 strict measures necessary to reduce or totally eliminate the microbial load of indoor air of this
216 hospital wards and units (Awosika *et al.*, 2012)

217 **CONCLUSION**

218 This investigation has been able to identify and prove the sensitivity patterns of
219 microorganism isolated from hospital environment surfaces. The study has shown that all the
220 hospital environmental surfaces examine in the course of the study in Akure, Nigeria were
221 contaminated with one or more microorganisms.
