

1 Factors Related to Deaths of Under 5 Years Old Children in Dar Alsalam Area-Khartoum- 2 Sudan

3 Abstract

4 **Objectives:** This study is done to identify factors affecting under five mortality in Dar Alsalam
5 area, Khartoum.

6 **Material and Method:** A community based cross-sectional study was carried out in Dar
7 Alsalam, Khartoum during March- April 2012, square 25. A total of 240 women in reproductive
8 age who had an experience of child death were interviewed. The data was collected by semi-final
9 medical students using structured questionnaire. Two stage cluster sampling was used to select
10 the households.

11 Data Analysis

12 Data was summarized using descriptive statistics and logistic regression analysis was carried out
13 to identify factors associated with under-five mortality.

14 Results

15 Age of 156 (65%) of the deceased children was less than one year, while the age of 84 (35%)
16 was between one and five years. The age of (25%) of the mother at the time of their child birth
17 was below 18 years. The majority of the mothers (70.8%) were illiterate, 74.2% were working
18 and 80% were married. Of the children 51.7 were males and for 74.2% of them the birth interval
19 was less than 2 years. Only 16.7% were breast fed for more than two years while the rest
20 (83.3%) were breast fed up to 2years. Only 34.2% of the deceased children had completed their
21 vaccination, and 68.3% had been admitted to hospital more than once before death.

22 Half of the families have piped water in their houses, 75.8% of the houses there are pit latrines
23 and 68.3% there is electricity supply.

24 Logistic regression analysis identified incomplete vaccination, not employed mothers and having
25 no latrines in the house as the factors related to the death of children between 1-5 years than
26 those below one year.

27 Conclusion

28 Under-five mortality in low socioeconomic areas is associated with Low family income,
29 mother's illiteracy, early marriage and absence of latrines in the houses. Keywords

30 **Key Words:** Factors, Under Five Mortality, Dar Alsalam, Khartoum.

31 1. Introduction

32 Under-5 mortality (U5M) is often used as an indicator of population health and performance of
33 the health system of the country ⁽¹⁾. U5M rate declined from 1.2% per year between 1990 and
34 1995, to 3.9% per year between 2005 and 2012 ⁽²⁾. In spite of this substantial drop in global child

35 mortality rate, about 6.6 million children still die every year before their fifth birthday worldwide
36 which implies 18,000 under-five children die each day ⁽²⁾. U5M includes deaths that occur
37 between birth and age five ⁽³⁾.

38 Under-5 mortality is unacceptably high in many developing countries, the burden of which is
39 mainly borne by the poor ⁽⁴⁾. About 41% of child deaths occur in sub-Saharan Africa ⁽⁵⁾. Most of
40 the neonatal mortalities are due to low birth weight and preterm labour and child mortalities are
41 due to simple preventable diseases such as diarrhoea, malaria, acute respiratory infection and
42 malnutrition ⁽⁶⁾.

43 Factors influence child health and survival includes maternal, child and house related factors.
44 Studies has shown association between mother age at birth, education, occupation and child
45 survival ^(7,8). Each year, adolescent girls worldwide give birth to 13 million infants ⁽⁹⁾, and infant
46 born to teenage mothers are known to be at particularly higher risk of dying ⁽¹⁰⁾. A study carried
47 out in Pakistan showed that children born to older women 30-39 years were exposed to
48 significantly higher neonatal and post natal mortality ⁽¹¹⁾.

49 Higher female literacy rates were strongly and significantly associated with lower U5M ⁽⁴⁾.
50 Mother education affects her skills in health care practices related to hygiene, nutrition,
51 contraception, preventative care and disease treatment ⁽¹²⁾. A strong associations had been
52 reported with maternal employment outside the home which significantly increases the odds of
53 U5M rate in a study carried out considering socioeconomic differences in neonatal, postnatal and
54 child mortality in 28 countries ⁽¹³⁾. A study done in rural Northern Ghana showed that married
55 women were less likely to experience child death than single parents ⁽¹⁴⁾.

56 Child related factors that affect child mortality include birth interval, breastfeeding, vaccination
57 and admission to hospital. Health related behaviors, such as birth spacing is important risk
58 factors for child mortality ⁽¹⁵⁾. There is high mortality rate when there is short birth interval ⁽¹⁶⁾.
59 A study carried out in Pakistan showed that breastfeeding has numerous bio-demographic, social,
60 and economic effects and it affects the health and nutritional status of both, the mother and child
61 ⁽¹¹⁾. A study done in India showed that breastfeeding had reduced child mortality by 70% ⁽¹⁷⁾.
62 Infants aged 0–5 months who are not breastfed have seven-fold and five-fold increased risks of
63 death from diarrhea and pneumonia, respectively, compared with infants who are exclusively

64 breastfed.(18) At the same age, non-exclusive rather than exclusive breastfeeding results in more
65 than two-fold increased risks of dying from diarrhea or pneumonia ⁽¹⁸⁾. Immunization is
66 important factor that affects U5M. A study done in Malakal Town, Southern Sudan showed
67 significant association between immunization and child mortality ⁽¹⁹⁾.

68 Environmental conditions have long been considered to have a significant influence on child
69 mortality. Such conditions include access to sanitation, source of drinking water, source of
70 energy and type of dwelling ⁽¹²⁾. Studies conducted have shown strong association between
71 access to clean water, sanitation and clean source of energy with infant and child mortality ⁽²⁰⁾.
72 The effects of these factors are so interlinked that they should be assessed together rather than
73 individually. Child mortality rates, more than doubled where the source of drinking water was
74 other than piped water and where poor sanitation existed child mortality rates are higher ⁽¹²⁾.

75 Sudan is classified as having made insufficient progress to achieve MDG-4 ⁽²¹⁾. The infant
76 mortality rate is 60 per 1,000 live births and the under-five mortality rate is 82 deaths per 1,000
77 live births and. the neonatal mortality rate is also high ranging from 34 to 47 per 1,000 births ⁽²²⁾.
78 Dar Alsalam is a settlement established in 1991 to accommodate the displaced that migrated to
79 Khartoum mainly from North Kurdofan as a result of the 1985 famine ⁽²³⁾.The settlement is
80 located to the west of Omdurman, one of the three towns that constitute Khartoum the capital of
81 Sudan. Population who live in these settlement neither enjoy the same health care services as
82 similar infrastructure as other formal urban areas, nor having proper environmental and housing
83 conditions. This is why this study is carried to identify factors related to U5M in this settlement.

84 **2. POPULATION AND METHODS**

85 **2.1 Study Design**

86 This is a descriptive community-based cross sectional study.

87 **2.2 Study Area**

88 The study was carried out in DarAlsalam area, west Omdurman, Khartoum locality. Dar alsalam
89 area is 32000 square meters and consisted of 53 blocks with a population size of 11,000. The
90 study area was block number 25 which was randomly selected. It consists of 2000 household.

91 2.3 Study Population

92 Mothers in reproductive age 15-49 years, resident of block number 25 in Dar Alsalam area. The
93 included study mothers were those with past history of at least one dead under five (U5) child
94 during her residency in Dar Alsalam and within the last five years.

95 2.4 Sampling and Sample Size

96 2.4.1 Sample Size

97 Sample size was calculated according to the following equation:

$$98 \quad n = \frac{Z^2 pq}{d^2} * de \quad \text{Where;}$$

99 n = the desired sample size

100 Z= standard normal deviate=1.96

101 P = the prevalence of occurrence of U5 Child deaths, 80 per 1000 live births according to Sudan
102 Household Survey(SHHS) in 2006⁽²⁴⁾.

103 q = (1- p) = 1-0.080=0.92

104 d = the desired margin of error = 0.05

105 de= the design effect for two stage cluster sample = 2

106 Therefore; n =226 mothers

107 To avoid the replacement in case of missing data, the sample size was increased by 6% to give a
108 total of 240 mothers.

109 2.4.2 Sampling Technique

110 It was two stage cluster sampling. First stage: one block was selected randomly from the 53
111 blocks in Dar Alsalam area; block number 25. Second stage: the households within block
112 number 25 were selected by systematic random sampling at interval of 8th household. The first
113 household was randomly selected from the center of the block and thereafter every 8th

114 household was visited. In cases of absence or refusal to participate, neighboring house was
115 chosen.

116 **2.5 Tools and data Collectors**

117 Data collection tool was structured close ended questionnaire targeted the interview of mothers
118 having the dead child. The questionnaire was composed of four parts. The first part composed of
119 the characteristics of mothers having U5 dead child that included current age of the mother, age
120 of the mother at time of birth, education, occupation and marital status of the mother. The second
121 part composed of the dead child characteristics that included child age at time of death, sex, birth
122 interval from the previous child, history of breastfeeding, history of vaccination, and admission
123 to hospital before death. The third part contained the information about family income and
124 household characteristics included presence of electricity, latrines, and piped water.

125 The data collectors were fifth year medical students as part of complementary research project in
126 community medicine training curriculum during academic year 2012.

127 For the purpose of this study the following definitions⁽²⁾ was considered:

- 128 1. Infant mortality is defined as the death of a live born infant between birth and exact age one.
- 129 2. Under-5 mortality includes deaths that occur between birth and exact age five.
- 130 3. Birth interval, is defined as the length of time between two successive live births,

131 **2.6 Data management and analysis**

132 Data were cleaned and managed by the software SPSS version 20. Descriptive statistics were
133 presented. Logistic Regression was carried out to identify factors associated with under-five
134 mortality. Twelve factors were included in logistic regression model pre analysis; three maternal
135 factors, five factors related to dead child, three housing factors and family income. Confidence
136 level of 95% was selected to reflect the significance effect of the factors.

137 Ethical clearance was obtained from the ethical committee of Faculty of Medicine, University of
138 Khartoum. Permission was taken from the administrative unit of block 25 in Dar Alsalam area

139 before the start of the study. An informed consent was signed by the selected mothers before
140 the interview that reflected the confidentiality of the information

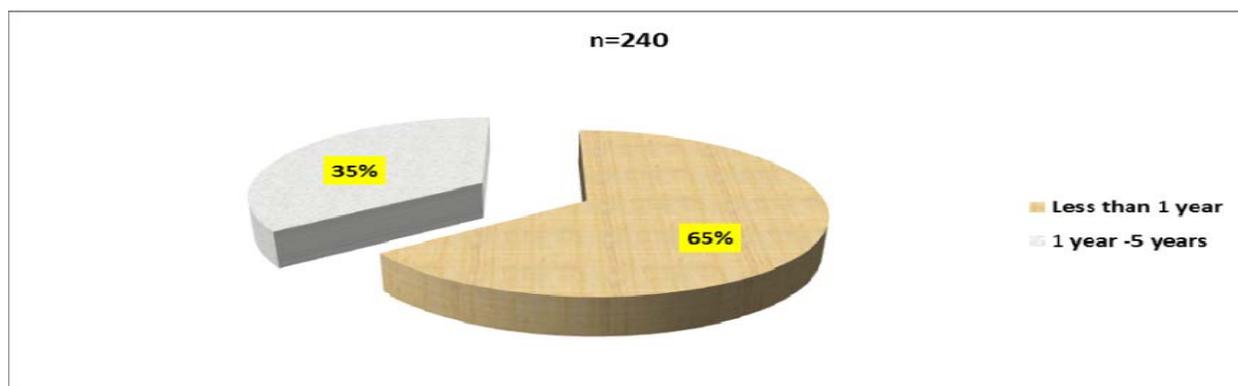

141 **3. Results**

142 Age distribution of deceased children revealed that(156) 65% were in the infancy period and (84)
143 35% were in the age group 1-5 years [Fig 1]. Characteristics of mothers with deceased children
144 had shown: Mothers at the age between 18-35 years when they delivered the deceased child
145 accounted to (160) 66.7% and (60) 25% were at the age below 18 years. One hundred and
146 seventy (70.8%) of the mothers were illiterate and 178 (74.2%) were having different working
147 status including freelance. [Table 1]

148 Gender characteristics of the deceased children had shown (124) 51.7% males and (116)
149 48.3% females [Table 2].Mothers had less than two years birth interval between the deceased
150 children and the previous one accounted to (178) 74.2% [Table 2]. Two hundred children
151 (83.3%) were breastfed up to 2 years, 158 (65.8%) did not complete their vaccination and (164)
152 68.3%of these children were admitted to hospital more than once before death [Table 2]. Half of
153 houses 120 (50%) of deceased children had access to piped water, 182 (75.8%) had inside pit
154 latrines and 164 (68.3%) had electricity. One hundred fifty eight (65.8%) Of the families were
155 having family income range between 50-150 SDG per week [Table 3].

156 Regarding factors associated with deaths of under-five children; twelve factors were included in
157 logistic regression model as independent factors and the dependent variable was the distribution
158 of age of deceased child into less than one year and 1-5 years. The factors were maternal age at
159 child birth, education, occupation, five factors related to deceased child [Table 2] and three
160 housing factors, and family income [Table 3]. The model yielded three factors related to the
161 death of child between 1-5 years only. The factors are; incomplete vaccination of the child has

162 eleven times the chance to death [Table 4]. Children of mothers without any working status have
 163 four times the chance to death [Table 4]. Children in houses without latrines have 3.5 times the
 164 chance to death [Table 4].

189 4. Discussion

190 The age of the mother at the time of delivery of the child is a known predictor of U5M⁽²⁵⁾. In this
191 study 60 (25%) of the mothers at the time of delivery of the child were below 18 years of age.
192 The result of the SHHS2006 showed that 36% of women in Sudan were married before the age
193 of 18⁽²⁴⁾. A study done in Northern Gana showed that infants born to teenage mothers are at
194 higher risk of dying⁽¹⁴⁾. A study done in Austria showed that higher mortality risk for infants of
195 younger mothers may be related to socioeconomic factors as well as biologic immaturity⁽²⁶⁾. A
196 study carried in England reported increased stillbirth and perinatal death in adolescent
197 pregnancy, beside low birth weight and preterm which reported to cause neonatal death⁽²⁷⁾. Two
198 third of the mothers' age in this study was 18-35 years when they gave delivery to their deceased
199 children. This finding is different from Infant Mortality Statistics from the 2004 Period where the
200 lowest rate of infant mortality is for mothers in their twenties and early thirties⁽²⁸⁾. The increase
201 of U5M in our study can be attributed to the socioeconomic status, nutritional health, quality of
202 prenatal care, and lifestyle of the mother, rather than to age alone⁽²⁹⁾.

203 The majority of the study population was illiterate. Infant mortality rates are known to decrease
204 with increasing educational levels ⁽³⁰⁾. The reasons may be that educated mothers are more likely
205 to receive antenatal care and more capable of gaining access to health care ⁽¹⁴⁾. Women with
206 more education tend to have higher income levels, and they have better opportunities for the
207 selection of the appropriate health care ⁽¹⁰⁾.

208 The majority of the women included in this study were working. In this sector of the town where
209 the study was carried out women work as house servants or daily laborers with low wages.
210 Mothers work can increase the family income which could positively affect the child survival
211 ⁽³⁰⁾. However, working outside the home, may affect negatively child survival by preventing the
212 mother from providing feeding and good care for the child ⁽¹³⁾. Logistic regression analysis
213 showed that the child between 1-5 years whose mother not working is approximately has four
214 times the chance to die than those below one year. After the first year mothers usually start
215 weaning their children and introducing food. Under low socioeconomic and poor environmental
216 conditions children are more likely to suffer from diarrhoeal diseases and other infections.

217 One hundred and fifty six 156 (65%) of the children died before their first birth day. Children in
218 sub-Saharan Africa have the highest risk of death in the first month of life ⁽³¹⁾. Infant mortality is
219 due to poor maternal health, inadequate care during pregnancy, inappropriate management of
220 complications during pregnancy and delivery, poor hygiene during delivery and the first critical
221 hours after birth, and lack of newborn care ⁽³²⁾. Causes of infant death after first year of life can
222 be caused by infectious diseases, such as pneumonia, tetanus, and malaria ⁽³³⁾.

223 One hundred and seventy eight (74.25%) of the deceased children in this study had a birth
224 interval of less than two years. A study done in Malakal, South Sudan showed that there is a

225 significant association between birth interval and infant and U5M ⁽¹⁹⁾. A study done in Pakistan
226 showed that birth interval is linked to prenatal care and child mortality. The same study showed
227 that babies born to mothers with shorter previous birth intervals who received prenatal care are
228 significantly more likely to have better survival chances during neonatal period than babies born
229 to mothers with the same short interval who did not receive prenatal care for the index child ⁽¹¹⁾.

230 All women included in this study breast fed their children for two years. Breastfeeding has been
231 recognized as a significant factor in ensuring child survival ⁽³⁴⁾. Breast feeding provides babies
232 with both the nourishment and the antibodies to fight infectious diseases. Infants aged 0–5
233 months who are not breastfed have seven-fold and five-fold increased risks of death from
234 diarrhoea and pneumonia, respectively, compared with infants who are exclusively breastfed ⁽³⁵⁾.
235 At the same age, non-exclusive rather than exclusive breastfeeding results in more than two-fold
236 increased risks of dying from diarrhoea or pneumonia ⁽³⁶⁾. Six to Eleven-month-old infants who
237 are not breastfed have an increased risk of deaths ⁽³⁷⁾. More than two third the deceased children
238 (68.3%) were admitted to hospital more than once before death. This could be explained by the
239 poor environmental and housing conditions which cause diseases like malaria, diarrhea and acute
240 respiratory illness. Rutstein 2002 showed that increase in the percentage of children receiving
241 medical attention for diarrhea, acute respiratory illness and fever was associated with decline in
242 U5M ⁽⁸⁾.

243 According to SHHS2006 only 56% of the population has access to clean water, and only 31% of
244 the population uses appropriate sanitation facilities ⁽²⁴⁾. In this study, logistic regression showed
245 children whose age (1-5) years living in houses having no latrine have 3.5 times a chance to die
246 than those below one year of age. Unhygienic and unsafe environments place children at risk of
247 death. Ingestion of unsafe water, inadequate availability of water for hygiene, and lack of access

248 to sanitation are known factors that contribute to the around 88% of deaths from diarrhea ^(38, 39).
249 Child mortality rates, more than doubled where the source of drinking water was other than
250 piped water ⁽²⁰⁾. Where poor sanitation existed child mortality rates are higher. A study in
251 Pakistan showed that families living in households with piped water connected in their houses
252 have a significantly lower post neonatal mortality than those families which depend on wells for
253 drinking water ⁽¹¹⁾.

254 In this study most of the population's weekly income range from 50-150 Sudanese pounds which
255 equals to 200-600 Sudanese pounds per month that is equivalent 16.7-50 dollars. A study carried
256 out to determine income below the poverty line and wage structure in the Sudan showed that the
257 household income at the poverty line for the Sudan for the year 2006 is equal to SD 52335 which
258 equivalent to 2005, \$US 227.5. Relating the estimated poverty line to the wage structure in the
259 public sector in the Sudan, the majority of the Sudanese people working in the public sector were
260 below the poverty line ⁽⁴⁰⁾.

261 **5. Conclusion**

262 U5M in low income countries is due to mothers' illiteracy, short birth interval, incomplete child
263 vaccination, low family income and poor housing conditions. Public health interventions,
264 improving living conditions and raising mother awareness towards family planning and U5M
265 causes are needed.
