# **EFFECT OF FERMENTATION ON THE NUTRIENT AND ANTI-NUTRIENT CONTENTS OF AFRICAN BUSH MANGO (*Irvingia gabonensis*) SEEDS**

6  
7

## **ABSTRACT**

**Aim:** Effect of fermentation on the nutrient and anti-nutrient contents of defatted and un-defatted African bush mango seeds.

**Study design:** The ground African bush mango seeds used in this study was divided into two portions; A, and B. Portion A was defatted while portion B was not defatted; both portions were fermented

**Place and Duration of Study:** Department of Microbiology and Chemistry Department, Federal University of Technology Akure, Ondo State between November 2017 and July 2018.

**Methodology:** Microbial analysis was carried out using the pour plate technique. The temperature, pH and total titratable acidity (TTA) were monitored throughout the fermenting period. Proximate, mineral and anti-nutrient contents of the samples were carried out using standard methods

**Results:** Seventeen microorganisms comprising 11 bacteria and 6 molds were isolated and identified as; *Staphylococcus aureus*, *Bacillus subtilis*, *B. cereus*, *S. epidermis*, *B. licheniformis*, *Micrococcus luteus*, *Proteus vulgaris*, *Enterococcus faecalis*, *Lactobacillus fermentum*, *L. plantarum*, *L. brevis*, *Aspergillus clavatus*, *A. flavus*, *A. niger*, *Rhizopus stolonifer*, *Penicillium chrysogenum* and *A. fumigatus*. The pH and TTA values reduced and increased respectively while the temperature varied significantly as the fermentation day increases. The non-defatted fermented sample showed increase in protein (10.34-12.09%), moisture (6.98-7.84%) and carbohydrate contents (24.98-29.20%); while there was a reduction in the ash (3.91-2.93%), fibre (1.55-1.30%) and fat (52.24-46.64%) contents. The defatted fermented sample showed an increase in the protein content (17.39-26.44%) while there was a reduction in the moisture (26.60-26.46%), carbohydrate (41.02-38.96%) ash (4.07-3.01), moisture (26.60-26.46%), fat (9.44-4.02%) and fibre contents (1.48-1.11%). The mineral composition of the fermented samples increased significantly when compared to the raw samples. The anti-nutrient content of the samples decreased significantly with fermentation.

**Conclusion:** This study revealed that African bush mango seeds can be defatted and fermented to produce food of enhanced nutritional value

## **1. INTRODUCTION**

12  
13  
14  
15  
16  
17  
18  
19

Trees and shrubs with medicinal and nutritional potentials proliferate in Nigeria and several of these plants have fruit and seeds which have been identified to be of nutritional relevance [14]. Mostly in developing countries, seeds are prominent features in the peasant dietary and in countries where the diet is plant based, oilseeds are becoming valuable sources of nutrient for man [7]. Attention has therefore been focused on under-utilized local seeds for possible development and use [14]. *Irvingia gabonensis* (Aubry-Lecomte ex O'Rorke) Baill is an economic food tree of West and Central Africa which belongs to the genus *Irvingia* within the family Irvingiaceae [2,21]. The genus *Irvingia* comprises of seven specie out of which only *Irvingia gabonensis* and *Irvingia excelsa* (*wombulu*) which are

20 frequently mistaken for each other are the only varieties identified in Nigeria and are subject of  
21 several transaction and some physiochemical studies [12,14,17]. The term African bush mango  
22 refers to these two economically most important Irvingia species that occur in the humid lowland  
23 forests of West and Central Africa and can be differentiated in that their flesh can either be sweet  
24 and edible (*Irvingia gabonensis*) or bitter and inedible (*Irvingia excelsa*) [6].

25 African bush mango bears edible mango-like fruit which is made up of the fleshy part and the nut,  
26 which consists of a hard shell and the kernel/seed. Its seeds have an outer brown testa (hull) and two  
27 white cotyledons which are especially valued for being rich in fat and protein [2,15]. The seed has  
28 nutritive, medicinal and industrial benefits and are richer in lipids than other oil seeds and legumes  
29 [22]. They also serve as source of human food and constitute important part of the diet in Nigeria as  
30 they are good source of vitamins and minerals. The ground seeds are used as thickening agents in  
31 soups and the oil can be processed into soap, cosmetics or pharmaceuticals [2]. It has been reported  
32 that ethno-medicinal treatments utilize other parts of the tree, like the bark, kernels, leaves, or roots  
33 for a variety of ailments [15]

34 Fermentation is one of the oldest biotechnologies used in the enhancement of the nutrient content  
35 and preservation of food through the biosynthesis of vitamins, essential amino acids and proteins,  
36 fibre digestibility and degrading anti-nutritional factors [12]. Fermented foods constitute an important  
37 part of the world's diet and are estimated to provide about 20-40% of human food supply. Chemical  
38 compounds, which are end products of fermentation process are not only enjoyed and tasty to a large  
39 number of people of different ethnic groups, it has also been noted that no single group or category of  
40 foods or food products are as important as fermented foods and have been relative to man's  
41 nutritional well-being throughout the world [14,19]. In order to maximize the nutritional benefits of  
42 African bush mango seeds and owing to the fact that not enough research has been carried out on  
43 the defatted seeds, it became necessary to determine the effect of fermentation on both the defatted  
44 and un-defatted seeds. The objective of this research is to determine the effect of fermentation on the  
45 nutrient and anti-nutrient contents of African bush mango seeds.

## 46 **2. MATERIALS AND METHOD**

### 47 **2.1 Collection of Samples**

48 African bush mango seeds used for this study were obtained from "Oja-oba" a local market in Akure,  
49 Ondo State, Nigeria. The samples were transported to the laboratory in clean low density  
50 polyethylene bags.

### 51 **2.2 Processing of African bush mango seeds**

52 The seeds were sorted by removal of stones and other foreign materials. They were surface sterilized  
53 by dipping in 90% ethyl alcohol for 60seconds, rinsed in several changes of sterile distilled water and  
54 then grinded using mortar and pestle.

#### 55 **2.2.1 Defatting of the sample**

56 A portion of the ground seed was defatted using the soxhlet extraction method as described by  
57 AOAC, 2012. All the glass apparatus were rinsed with the solvent which is n-hexane after appropriate  
58 cleaning. The apparatus was set up by placing the distillation flask filled with n-hexane up to three  
59 quarters on the heat source. The thimble containing ground African bush mango seeds was loaded  
60 into the main chamber of the soxhlet extractor which was placed on the distillation flask and a  
61 condenser was placed on top. The solvent is heated to reflux and the evaporated solvent passes  
62 through the side tube of the extractor and condenses in the condenser fitted at the top of the  
63 extractor. The condensed hot solvent runs into the thimble and soaks the sample extracting its  
64 constituent. The chamber holding the thimble becomes full and the solvent siphons down to the flask.  
65 This process was repeated till extraction is complete usually between 5-7hours

### 66 **2.3 Fermentation of samples**

67 The submerged state fermentation was employed for the fermentation of the African Bush Mango  
68 seeds in different ratios due to the nature of the samples for 96 hours. The un-defatted seeds were  
69 soaked in sterile distilled water in ratio 1:5 while the defatted sample in the ratio 1:20.

## 70 **2.4 Microbiological Analysis of the Samples**

71 Bacteria and fungi were evaluated using nutrient agar (NA) and potato dextrose agar (PDA)  
72 respectively while De Man Rogosa and Sharpe agar was used to isolate lactic acid bacteria.  
73 Techniques were enumerated by using appropriate serial dilution and pour plate techniques. The  
74 bacterial culture was incubated at 37°C for 18 to 24 hours, fungal plates were inverted and incubated  
75 at 24°C for 48 to 72 hours. De Man Rogosa and Sharpe agar plates were incubated at 32°C for 18-  
76 24 hours anaerobically. The organisms were characterized based on biochemical and morphological  
77 observations according to the method of [9]. Fungi isolates were identified according to [16]

## 78 **2.5 Determination of pH, Temperature and Total Titratable Acidity (TTA)**

79 The pH, temperature and TTA of the samples were monitored throughout the fermentation period.  
80 The pH was ascertained using the pH meter metrom E520 which was calibrated using buffer solution  
81 of pH 4.0, 7.0 and 9.0. 1g of the sample was homogenized in 10ml of distilled water and the pH glass  
82 electrode was inserted for 2 minutes ensuring that the glass electrode did not touch the bottom of the  
83 bottle. The resultant value was read on the meter scale and then recorded in triplicate. The  
84 temperature was determined using a mercury in-bulb thermometer which was dipped into the  
85 fermenting sample for about 3 minutes under sterile condition, it was then withdrawn and the  
86 temperature was read and recorded in triplicate. TTA was estimated according to the official methods  
87 of analysis [5]. 2g of each sample was weighed into 20ml of distilled water in different beakers, 2  
88 drops of phenolphthalein was added as an indicator and then 150ml of the aliquots were titrated  
89 against 0.1N NaOH.

## 90 **2.6 Determination of Proximate composition**

91 The samples were analysed daily for Moisture, Ash, Fat, Protein, Crude fiber and Carbohydrate  
92 according to the method described by [5]. Moisture content was determined by drying to constant  
93 weight at 105°C in an oven, ash by ignition at 55°C in a muffle furnace, fat content by soxhlet  
94 extraction with hexane, nitrogen by micro-Kjedahl and the percentage nitrogen was converted to  
95 crude protein by multiplying by 6.25, crude fibre by acid/alkali digestion methods and carbohydrate  
96 determined by difference.  
97

## 98 **2.7 Mineral Determination**

99 The mineral composition of the samples throughout the fermentation period was carried out on the  
100 product obtained by dry-ashing the sample in a muffle furnace at 550°C. The ashed samples were  
101 cooled in the desiccator, dissolved in 10ml of 10% HCL and was made up to 50 ml with deionized  
102 water in a volumetric flask. Sodium and potassium were determined using a flame photometer  
103 (photometer (model 405, coming UK) while calcium (Ca), zinc (Zn), iron (Fe) and magnesium (Mg)  
104 were determined by atomic absorption spectrophotometer (AAS)[5].

## 105 **2.8 Anti-Nutrient Determination**

106 Phytate tannin was determined using the method of [5], oxalate content was by the titrimetric  
107 method as modified by [4] while saponin was determined by the spectrophotometric method as  
108 described by [8]

109

## 110 **2.9 Statistical Analysis**

111 All analyses were performed in triplicates. The data obtained were subjected to one way analysis of  
112 variance (ANOVA) while differences in mean were determined using Duncan's New Multiple Range  
113 Test (DMRT). All data analyses were done with SPSS 23.0 version.

## 114 **3. RESULTS AND DISCUSSION**

### 115 **3.1 Microbial Growth during Fermentation of African bush mango seeds**

116 Seventeen (17) microorganisms were isolated from African bush mango seeds which were identified  
117 as shown on tables 4 and 5. Eleven (11) bacteria: *Bacillus subtilis*, *Bacillus cereus*, *Staphylococcus*  
118 *epidermis*, *Bacillus licheniformis*, *Micrococcus luteus*, *Proteus vulgaris*, *Enterococcus faecalis*,

119 *Lactobacillus fermentum*, *Lactobacillus plantarum*, *Lactobacillus brevis* and *Staphylococcus aureus*.  
120 Six fungi: *Aspergillus clavatus*, *Aspergillus flavus*, *Aspergillus niger*, *Penicillium chrysogenum*,  
121 *Rhizopus stolonifer* and *Aspergillus fumigatus*.

### 122 **3.2 Changes in Bacteria Population during Fermentation of African bush mango** 123 **seeds**

124  
125 Fig. 1 shows the changes in the bacteria population of the samples during fermentation for 96hours.  
126 The total bacterial count for both samples (Un-defatted and defatted) increased at 24hours and 48  
127 hours then decreased at 72hours and 96hours. For sample A (Un-defatted sample) the bacteria  
128 population increased with time till 48hours with values  $7.00 \times 10^5$  cfu/ml,  $12.02 \times 10^5$  cfu/ml and  $15.97$   
129  $\times 10^5$  cfu/ml while at 72 hours and 96 hours of the fermentation it decreased to  $9.01 \times 10^5$  cfu/ml and  
130  $6.01 \times 10^5$  cfu/ml respectively. The bacteria population for sample B (Defatted sample) also increased  
131 with time till 48 hours with values  $4.00 \times 10^5$  cfu/ml,  $9.02 \times 10^5$  cfu/ml,  $14.02 \times 10^5$  cfu/ml, while a  
132 decrease was recorded at 72hours and 96 hours with values  $6.97 \times 10^5$  cfu/ml,  $4.00 \times 10^5$  cfu/ml.

### 133 **3.3 Changes in Lactic Acid Bacteria Population during Fermentation of African** 134 **Bush Mango Seeds**

135 Fig. 2 shows the total lactic acid bacterial count for the African bush mango seeds during fermentation  
136 for 96hours. There was no Lactic acid bacteria growth at the initial hour for both sample however, the  
137 growth thereafter increased with increase in fermentation time. For sample A (un-defatted sample) the  
138 lactic acid bacteria population increased from 24 hours till 96 hours with values  $3.02 \times 10^5$  cfu/ml,  $5.97$   
139  $\times 10^5$  cfu/ml,  $13.97 \times 10^5$  cfu/ml and  $16.02 \times 10^5$  cfu/ml respectively. The lactic acid bacteria  
140 population for sample B (defatted sample) also increased from 24hours till 96 hours with values  $2.00$   
141  $\times 10^5$  cfu/ml,  $5.02 \times 10^5$  cfu/ml,  $11.97 \times 10^5$  cfu/ml and  $14.97 \times 10^5$  cfu/ml respectively.

### 142 **3.4 Changes in Fungi Population during Fermentation of African Bush Mango Seeds**

143 Fig. 3 shows the total fungal mean count for the African bush mango seeds during fermentation for 96  
144 hours. There was no fungal growth at the initial hour for both sample however, the growth thereafter  
145 increased with increase in fermentation time. For sample A,  $3.02 \times 10^5$  cfu/ml was observed at  
146 24hours,  $4.97 \times 10^5$  cfu/ml at 48 hours,  $9.02 \times 10^5$  cfu/ml at 72 hours and  $10.97 \times 10^5$  cfu/ml at 96  
147 hours. For sample B,  $2.97 \times 10^5$  cfu/ml,  $4.02 \times 10^5$  cfu/ml,  $6.97 \times 10^5$  cfu/ml and  $8.97 \times 10^5$  cfu/ml  
148 was observed from 24hours to 96hours respectively.

**Table 2. Characteristics of fungi isolated during fermentation of African bush mango seeds**

<b>Cultural characteristics</b>	<b>Morphological description</b>	<b>Probable fungi</b>
Blue-green colonies which appear to be generally coarse and smooth-walled	Uniseriate conidia, large club shaped vesicle	<i>Aspergillus clavatus</i>
Yellow-green colonies, rough walled stipes	Radiate conidia which later split to form loose columns, mature vesicles bearing phialides over their entire surface and conspicuously echinulate conidia	<i>Aspergillus flavus</i>
Colonies growth spread rapidly with fluffy and velvety in texture with aerial mycelia white at first, frequently developing dark-brown to black conidia heads	Dark brown conidia, conidiophores are long globose, vesicles that are completely covered with biserate phialides which are borne on brown metulae	<i>Aspergillus niger</i>
Blue-green colonies with yellow pigments	Brush-shaped conidiophores, subglobulus conidia, smooth stipe and flask-shaped phialide	<i>Penicillium chrysogenum</i>
White cotton-like fluffy mycelium	Non-septate hyphae, coenocytic twin sporangiospheres	<i>Rhizopus stolonifer</i>
Suede-like blue-green colonies that is smooth walled	Uniseriate and columnar conidial heads with the phalides limited to the upper two thirds of the vessicle and curving to be roughly parallel to each other	<i>Aspergillus fumigatus</i>

### 3.5 Bacteria occurrence during fermentation of African bush mango seeds

Results of the bacteria isolated during fermentation of African bush mango seeds are shown on **Table 3**. *Staphylococcus aureus* was isolated from sample A at 24 and 48 hours while it was isolated from sample B at 24, 48, 72 and 96 hours. *Bacillus subtilis* was isolated from sample A throughout the fermentation period while it was isolated from sample B at 0, 24 and 48 hours. *Proteus vulgaris*, *Bacillus licheniformis* and *Enterococcus faecalis* were isolated from sample A at 48 and 72 hours, and at 0, 24 and 48 hours respectively while *Bacillus cereus*, *Micrococcus luteus* and *Lactobacillus brevis* were isolated from sample B at 0, 24 and 48 hours, 24, 48 and 72 hours, 48, 72 and 96 hours respectively. *Staphylococcus epidermis* was isolated from sample A at 0, 24 and 72 hours, from sample B at 0, 24 and 96hours. *Lactobacillus plantarum* and *Lactobacillus fermentum* were the dominant microorganisms isolated from samples A and B at 24, 48, 72 and 96 hours.

### 3.6 Fungi Occurrence during Fermentation of African Bush Mango seeds

Results of the fungi isolated during fermentation of African bush mango seeds are shown on **Table 4**. *Aspergillus niger* was isolated from sample A at 48,72 and 96 hours while *Aspergillus clavatus* was isolated from sample B at 24, 48 and 72hours. *Aspergillus flavus*, *Pennicillum chrysogenum*, *Rhizopus stolonifer* and *Aspergillus fumigatus* were the most dominant microorganism in both samples at 48, 72 and 96 hours

### 276 **3.8 Changes in total titratable acidity during fermentation of African bush mango** 277 **seeds**

278 Variations in titratable acidity (TTA) during fermentation of African bush mango seeds are represented  
279 in Fig. 2. Sample A had TTA of  $3.8 \pm 0.01$  at 0 hour; this increased slightly to  $3.85 \pm 0.01$  and  $3.88 \pm$   
280  $0.02$  at 24 hours and 48 hours,  $4.02 \pm 0.01$  at 72 hours and finally to  $4.08 \pm 0.01$  at 96 hours. TTA for  
281 Sample B increased slightly from  $3.75 \pm 0.02$  at 0 hour to  $3.78 \pm 0.01$  at 24 hours, increased to  $3.82 \pm$   
282  $0.01$  at 48 hours,  $3.95 \pm 0.02$  at 72 hours and finally to  $4.0 \pm 0.01$  at 96 hours.

### 3.9 Changes in temperature during the fermentation of African bush mango seeds

299

Fig. 3 shows the variation of temperature during the fermentation of African bush mango seeds. The temperature for sample A at 0 and 24 hours is  $32 \pm 0.01$  and  $32 \pm 0.02$  respectively. This increased to  $34 \pm 0.01$  at 48 hours, decreased to  $28 \pm 0.01$  at 72 hours and finally increased to  $30 \pm 0.02$  at 96 hours. Sample B had a temperature of  $32 \pm 0.02$  and  $32 \pm 0.01$  at 0 and 24 hours respectively. An increase of  $34 \pm 0.02$  was recorded at 48 hours and a decrease of  $29 \pm 0.01$  at 72 and 96 hours

324 **3.10 Changes in proximate composition during fermentation of African bush mango**  
325 **seeds**

326 Fig. 4 shows the proximate composition of the samples throughout the fermentation period. There  
327 was a significant increase in the moisture content of sample A (UDS) from  $6.98 \pm 0.01$  to  $7.84 \pm 0.02$  at  
328 96 hours while there was a slight decrease in that of sample B (DS) from  $26.60 \pm 0.02$  to  $26.46 \pm 0.01$  at  
329 96 hours. There was a significant decrease in the ash, fat and fibre content of both samples at the  
330 end of the fermentation period. Ash content for sample A reduced from  $3.91 \pm 0.04$  to  $2.93 \pm 0.03$  while  
331 there was a reduction in that of sample B from  $4.07 \pm 0.12$  to  $3.01 \pm 0.07$ . The fat content for sample A  
332 reduced from  $52.24 \pm 0.04$  to  $46.64 \pm 0.02$  while a reduction of  $9.44 \pm 0.02$  to  $4.02 \pm 0.05$  was recorded for  
333 sample B. Fibre content for sample A reduced from  $1.45 \pm 0.03$  to  $1.30 \pm 0.01$  while a significant  
334 reduction of  $1.48 \pm 0.04$  to  $1.11 \pm 0.02$  was recorded for sample B. A significant increase was recorded  
335 in the protein content for both samples at the end of the fermentation period. The protein content for  
336 sample A increased from  $10.34 \pm 0.08$  to  $12.09 \pm 0.04$  while for sample B increased from  $17.39 \pm 0.03$  to  
337  $26.44 \pm 0.12$ . There was a significant increase of  $24.98 \pm 0.04$  to  $29.20 \pm 0.03$  in the carbohydrate content  
338 of sample A while there was a significant decrease of  $41.02 \pm 0.02$  to  $38.96 \pm 0.12$  in that of sample B  
339 (Fig. 4)

340 **3.11 Changes in mineral composition during fermentation of African bush mango**  
341 **seeds**

342 There was a significant increase in the sodium, calcium, zinc and magnesium contents of both sample  
343 A (UDS) and sample B (DS) at the end of the fermentation period. The sodium content for sample A  
344 increased from  $34.14 \pm 0.08$  to  $42.12 \pm 0.01$  while that of sample B increased from  $38.00 \pm 0.01$  to  
345  $44.46 \pm 0.01$ . The calcium content for sample A recorded an increase of  $20.23 \pm 0.01$  to  $29.34 \pm 0.01$   
346 while that of sample B increased from  $25.97 \pm 0.04$  to  $34.12 \pm 0.01$ . A significant increase of  $5.34 \pm 0.01$   
347 to  $6.13 \pm 0.01$  was recorded for the zinc content of sample A while that of sample B increased from  
348  $7.12 \pm 0.01$  to  $8.67 \pm 0.01$ . For sample A, magnesium increased from  $50.21 \pm 0.00$  to  $61.21 \pm 0.01$  while it  
349 increased from  $55.45 \pm 0.01$  to  $66.33 \pm 0.01$  for sample B. There was a significant decrease of  
350  $41.42 \pm 0.01$  to  $38.81 \pm 0.00$  in the potassium content of sample A while a significant increase of  
351  $52.22 \pm 0.00$  to  $58.23 \pm 0.01$  was recorded in that of sample B. The iron content in both samples  
352 decreased significantly at the end of the fermentation period for both samples (Fig. 5).

353 **3.12 Anti-nutritional composition of African bush mango seeds**

354 The anti-nutrient content of the samples decreased significantly with increase in fermentation time.  
355 The highest phytate content (mg/g) was recorded in sample A (un-defatted African bush mango  
356 seeds) at the start-up of the fermentation with a value of  $30.46 \pm 0.02$  while the least phytate content  
357 was recorded in sample B (defatted African bush mango seeds) at 96 hours of fermentation with a  
358 value of  $13.68 \pm 0.04$ . Tannin content recorded the highest in sample B at the start-up of the  
359 fermentation with a value of  $4.05 \pm 0.02$  and lowest at 96 hours with value  $0.55 \pm 0.01$ . At the initial,  
360 sample B has the highest oxalate value of  $5.76 \pm 0.00$  and it also has the lowest oxalate value of  
361  $1.54 \pm 0.03$  at 96 hours. Saponin content recorded the highest value of  $33.46 \pm 0.02$  in sample A at  
362 the initial while sample B recorded the lowest value of  $2.16 \pm 0.01$  at 96 hours. (Fig. 6)

416  
417 **4. DISCUSSION**

418 Many factors contribute to the presence of microorganisms in foods, the endogenous presence and  
419 cross contaminations are the factors most pointed out as being the sources. However the diverse kind  
420 and number of microorganisms on any food depends on various factors of which the pH, moisture and  
421 nutrient composition of the food are major factors [23]. In this study, a total of seventeen  
422 microorganisms were isolated from African bush mango seeds. These organisms have been found to  
423 be responsible for the fermentation of some legumes as reported by [12,27]

424 *Bacillus species* is the predominant bacteria flora isolated from the samples and this could be as a  
425 result of their ability to survive in slightly acidic and alkaline environment. Moreover, they are known to  
426 have better competitive ability compared to other bacteria species present in the same environment  
427 [1]. *Aspergillus* and *Rhizopus species* were isolated from fermenting mango peel reported by [30] as  
428 also isolated from the African bush mango seeds in this study. The presence of *Staphylococcus*  
429 *epidermis*, *Enterococcus faecalis* and *Proteus vulgaris* could have been as a result of contamination  
430 during handling and processing, this is in line with the work of [25] who reported that the presence of  
431 *Staphylococcus sp.* during the fermentation of popcorn and groundnut composite flour.

432 The decrease observed in bacteria load after 48hours of fermentation may be as a result of nutrient  
433 depletion and some bioactive substances which may have produced an inhibitory effect on other  
434 organisms present in the medium. This is in line with the report of [1] who reported a decrease in  
435 bacteria load after 48hours liquid fermentation of Kersting's groundnut. The significant increase

436 observed in the fungal load during fermentation may be due to the ability of fungi to thrive in lower pH  
437 and water activity even more than bacteria.

438 The reduction in pH observed in this study could be attributed to the production of acids by the  
439 fermenting microorganisms and the observed increase in titratable acidity could be due to the  
440 dominance of the fermenting medium by lactic acid bacteria which degrade carbohydrates resulting in  
441 acidification. This observation is in agreement with earlier studies by [18,26].

442 Proximate compositions are generally considered to be the approximation of the nutrient composition  
443 of all human diets and fermentation had effect on the proximate composition of African bush mango  
444 seeds as observed during the study. The increase in the moisture content in the Un-defatted sample  
445 after fermentation agrees with the report of [2] and he suggested that it could be due to the secretion  
446 of free water molecules due to the activities of the fermenting microorganisms in the medium. The  
447 decrease observed in the moisture content of the defatted sample as fermentation time increased was  
448 also observed by [24], who reported that as fermentation time increased, moisture content decreased  
449 while the total solid content in fermenting soymilk increased. The high protein content recorded in this  
450 study suggested that African bush mango seeds might be a good source of dietary protein as  
451 reported by [2]. The increase in protein content could as a result of proliferation of the microbial  
452 biomass during fermentation due to the release of extracellular enzymes by the microorganisms or  
453 their ability (microorganisms) to synthesize amino acids and proteins [11].

454 The increase in the carbohydrate content of the un-defatted sample may be attributed to the decrease  
455 in moisture content of the African bush mango seeds as fermentation time increased. This is in line  
456 with the report of [20] who reported an increase in the carbohydrate content of cocoyam flour as  
457 fermentation time increased. However, the reduction in the carbohydrate content of the defatted  
458 sample might be as a result the microorganisms utilizing some of the sugars needed for their growth  
459 and metabolism by secreting saccharolytic enzymes which broke down the complex carbohydrates  
460 into smaller units like sugars and alcohols. Carbohydrate will most likely be their main source of  
461 energy since the fat content has been greatly reduced by defatting. This agrees with the work of [28]  
462 who reported a reduction in the carbohydrate content after fermentation of cowpea-plaintain flour  
463 blend and popcorn-groundnut flour respectively.

464 Fat is one of the major components of food that provides essential energy and lipids. Lipid  
465 constituents are the major determinants of overall physical characteristics of food such as aroma and  
466 texture [28]. The decrease in the fat content of both samples after fermentation might be attributed to  
467 the increased activities of lipolytic organisms releasing enzymes during fermentation which hydrolyses  
468 fat components (triacylglycerol) into fatty acid and glycerol. This conforms to the result [24] who  
469 reported that fat content of soymilk was found to decrease as fermentation time increased.

470 Ash is an inorganic residue remaining after the removal of water and organic matter which provides a  
471 measure of total amount of minerals in the food component [28]. Reduction in the ash content of the  
472 samples corresponds to the work of [20] who reported a decrease in the ash content of cocoyam flour  
473 and ascribed it to possible leaching of soluble mineral elements into fermenting medium or due to  
474 general activities of the fermenting microorganisms whose enzymatic activity resulted in breakdown of  
475 the food components into their absorbable forms. [3] also reported reduction in ash contents while  
476 fermenting lima bean seeds. The reduction in crude fibre of the samples could be attributed to  
477 enzymatic breakdown of the fibre by the fermenting microorganisms which agree with the report of  
478 [27] who recorded a reduction in crude fibre of sorghum and pumpkin blend after fermentation.

479 The reduction observed in the anti-nutrient content of African bush mango seeds after fermentation  
480 had been reported in many fermented legumes [10,31]. A wide range of microflora has been known to  
481 possess phytase activity [29]. The decrease in phytate content could be attributed to the activity of the  
482 endogenous phytase enzyme from the sample and inherent microorganisms which are able to secrete  
483 the hydrolytic enzyme (phytase) capable of degrading the phytic acid in the fermented African bush  
484 mango seeds. Some lactic acid bacteria and fungi such have been known to secrete phytases which  
485 could degrade phytate to considerable levels. The significant reductions in the anti-nutrient contents  
486 of the sample are welcome development because the minerals and other nutrients bound to them  
487 become more readily available [3]. The decrease in tannin could be attributed to presence of

488 microorganisms capable of secreting the enzyme tannase which could degrade tannin content to  
489 considerable levels. Reduction in the tannin content of African oil bean seed was observed by [13].

490 Fermentation has been reported to increase the mineral contents of certain food products. [24]  
491 reported an increase in the calcium, iron and magnesium contents in soymilk with increase in natural  
492 fermentation. [12] also reported an increase in magnesium, calcium, sodium and phosphorus of  
493 African bush mango seeds after fermentation. The significant decrease in the potassium content of  
494 the non-defatted sample, iron content of the non-defatted and defatted samples after fermentation has  
495 been reported in various reports and can be attributed to their utilization by some fermenting  
496 microorganisms for their growth and metabolism. It was noted that fermented sample was rich in  
497 some essential minerals which perform various functions in the body [2,24]

## 500 5. CONCLUSION

501  
502 This study on the effect of fermentation on the nutrient and anti-nutrient content of African bush  
503 mango seeds revealed that there was improvement in the nutritional quality of the samples after  
504 fermentation compared with the raw samples. The defatted sample has a higher nutritional quality  
505 than the un-defatted sample. However the defatted fermented sample showed the most desirable  
506 nutritional qualities which suggest its relevance in human diet for improved nutritional benefits.
