2

3

67 **Abstract:**

8 The main objectives of the study were to identify the present status of agriculture along with the problem confronted by the farmers and to determine the present cropping pattern 9 followed by the farms under conservation agriculture. Data were collected from randomly 10 selected 91 farmers of three upazilla under Khulna region with the help of personal interview 11 method by using an interview schedule during January 2017 to May 2018. Data were 12 collected on fifteen selected categories of the farmers and the problem confronted by them. 13 Most of the respondents have small to medium sized cultivable lands. Bean, cauliflower, 14 cabbage, potato, Indian spinach, brinjal, tomato etc, were more extensively cultivated. 15 Maximum farmers belonged to medium practice of conservation agriculture while very few 16 of them had low or high practice. To determine the present status of agriculture data were 17 also collected from on the name of crop rotation, use of fertilizers and manures, intercultural 18 operation followed by the respondents, pest and disease infestation in the field under 19 cultivation. Out of all independent variables, only extension media contact, level of education 20 21 and organizational participation of the farmers had showed positive significant relationship with conservation agriculture practice. Extension media contact and organizational 22 participation influence the extent of CA practices at farmers' field as confirmed by the 23 backward linear regression model. The vital problems of conservation agriculture practices 24 25 were lack of seed, high price of seed, lack of fertilizers, high price of fertilizer, impurity and high price of insecticides/ pesticides, lack of irrigation water, salinity, lack of knowledge etc. 26 To popularize the CA practices, Government should organize more training and 27 28 demonstration activities on CA involving block level extension workers as well as farmers 29 plus strengthening research-extension-farmers linkage.

I. Introduction

- 34 Feeding for the large population of the country like Bangladesh is the prime concern of
- 35 Bangladeshi government. However manufacturing quality food maintaining property of soil
- 36 health for future generation could be a potential future concern. Future use of
- 37 chemical fertilizer and pesticides while mistreatment organic compounds resulted soil
- degradation and initiate decreasing trend of soil productivity (Kafiluddin and Islam 2008).

39	Intensified HYV of rice and other crops cultivated in the local land to feed the huge	
40	population of the country, has led to huge amount of nutrients loss from the soil	
41	(Akteruzzaman et al., 2012). The outcome of this intensified rice based agriculture on soil	Comment [s1]: et al.,
42	fertility, soil microbial activity and lastly to our environment is severe (Uddin and Dhar,	
43	2016). An increased cropping intensity of 1.90 (BBS, 2012) with traditional rice based	
44	cropping pattern covering most of the land (Rashid et al., 2014) influence the situation	Comment [s2]: et al.,
45	further. That's why the incorporation of sustainable and conservable techniques to	
46	commercial farming is becoming popular all over the world (Johansen et al. 2012).	Comment [s3]: et al.,
47	Bangladesh is a small country in Southeast Asia and also trying to adopt Conservational	
48	Agriculture (CA) considering its positive impact on soil health and also for the environment.	
49	Already minimum tillage and other conservation techniques are practicing in the country but	
50	not on large scale (Islam et al. 2011).	Comment [s4]: et al.,
51	Around 45.1 percent of total labor force of Bangladesh involved in Agriculture but now days,	
52	labour scarcity is increasing day by day (BBS, 2015) and labor wage is also very high	
53	(Statistical Bulletin, 2013) which create bad impact on total production budget. Already	
54	minimum tillage and other conservation techniques are practicing in the country but not on	
55	large scale (Islam et al. 2011). CA is associate degree approach that reduces	Comment [s5]: et al.,
56	agricultural operational prices whereas increasing yields utilizing natural resources	
57	properly (Roy et al., 2009). With the follow of minimum tillage solely, prices of	Comment [s6]: et al.,
58	production may be move massive extent (Miah et al., 2010). The CA research in Bangladesh	Comment [s7]: et al.,
59	are few and previous research mainly focuses on adoption of different conservation	
60	agriculture practices (Dass, 2013). Research reports available in Bangladesh (Barma et al.,	Comment [s8]: et al.,
61	2014) revealed that wheat, maize, pulses, oilseeds, jute, rice can be established and grown	
62	successfully using CA technology. Farmers are accepted the conception of CA based on	
63	mostly tillage technologies considering the benefits of upper yields, reduced value of tillage	

Comment [s9]: et al.,

operation, and minimum work time between the crops (Hossain et al., 2015). But, practicing conservation agriculture is not yet studied well. So, a research work will be conducted by present status and combining different cropping pattern in the farm through conservation agriculture in the Khulna region of Bangladesh. The research will be performed using different crops such as rice (BR 23, BRRI dhan30, BRRI dhan40 and BRRI dhan41), wheat, white maize, sesame, sunflower, jute, kenaf, dhaincha, mung bean, chick pea, sorghum, different vegetables etc. The soil fertility level in the south-west region (Khulna) is especially poor in organic matter. The farmers of southwestern part of Bangladesh followed traditional agriculture day after day without considering modern technology such as conservation agriculture. Farmers and other stakeholders who are new or are at the initial stages of converting to CA require tangible evidence on the benefits and impacts of CA. The present study will be untaken by the following objectives. a) To investigate the present status of farming system in the Khulna region. b) To identify the existing cropping pattern in the study area. c) To identify the constraints and opportunities to adoption of CA in existing pattern in Khulna region. D) To suggest some policy guidelines for popularizing CA.

II. Methods and Materials

This study was a survey based research and confined to three upazila (Dumuria, Paikgachha and Botiaghata) of Khulna district, Khulna, located in the south-western region in Bangladesh. Khulna is situated between 21.38' and 23.10' north latitude and 88.58 east latitude and is 12 ft. above mean sea level (http://www.khulnacity.org/). This study was conducted into 4 types of areas such as high land, medium high land, medium low land and low land (shrimp farming area). The cultivators of the selected areas were treated as population of the study. Data were collected in random sampling technique where each

farmer is considered as the sampling unit and each farmer was treated as active population of the study. Out of all the farmers, 91 farmers were selected randomly as the sample 91 respondents. The interview schedule (IS) contained both simple and direct form of question to collect data on the selected variables. The interview schedule was pre-tested before final 92 93 collection of data. The farmers' family was selected as respondents. Data were collected with the help of the interview schedule by the researcher himself. Interviews were taken to the respondents at their homes, field or market during their leisure period. Data were collected from the respondents during January to May, 2015. Based on the practical and theoretical knowledge, the 10 characteristics of the farmers constituted the independent variables of the study. The characteristics of respondents which are treated as independent variables for the study are age, occupation, education, family size, experience in farming, annual income, farm size, organizational participation, Cosmopoliteness, extension media contact and knowledge in vegetables cultivation. Besides, data were also collected on the use of fertilizer and manures in the field, intercultural operation, pest and disease attack in the cultivation area. The dependent variables of the study were the problem confrontation on conservation agriculture practice and cropping pattern of the Khulna region. This problem was measured on the basis of their response to questions in the interview schedule. In this study, problem confrontation score was computed for each respondent as ascertained from his responses. Each respondent was asked to indicate his problem against selected 14 issues which were Lack Of seed, High Price of seed, Lack of Fertilizer, High Price of Fertilizer, Impurity of Insecticides/ Pesticides, High price of Insecticides/ Pesticides, High Incidence of Insect, Lack of Irrigation water, Increase salinity in soil, Lack of land due to Shrimp Culture, Salinity due to Shrimp Culture, Lack of Knowledge, Activities of extension 112 worker, Natural calamities. Cropping pattern means the proportion of area under various 113

crops at a point of time. This portion was measured by the 4 types of different selected study area like high land, medium high land, medium low land and low land. Different crops are grown in rotation on this selected study areas are Kharif I, Kharif II, Robi.

After completion of survey all the interview schedules were compiled for its data processing. At the beginning of the data processing all the qualitative data were converted into quantitative form by means of suitable code and score whenever necessary. Local units were converted into standard units. In several instance, Indies and scales were constructed through the simple accumulation of scores assigned to individual or pattern of attributes. Indices and scales are considered the efficient instrument for data reduction and analysis. All personal traits were categorized and arranged in simple tables for interpretation and discussion. Number, frequency, percentage, mean and standard deviation were used as descriptive statistics.

III. Results and Discussions

Comment [s41]: Delete

To finding of the study and interpretation of the results with necessary discussion has been presented in this chapter. The results of this study have been presented according to the objectives. This section is conveniently divided into three sections. The first section deals with the personal and socio-economic characteristics of the respondents. The second section isolates the problem faced by the respondents and finally, the third section deals with the existing cropping pattern present in the Khulna region of Bangladesh following conservation agriculture.

1 Facts on Selected Characteristics of the Respondents

1.1 Age of the respondents

Comment [s42]: R

137	Based on age, the respondents have been classified into three categories as shown in table 1.	Comment [s43]: T
138	The age of the respondents ranged from 25-75 years. It is indicate that the highest number of	
139	respondents (63%) belongs to the middle age group (31-50 years) followed by the young age	
140	group (15%) and only 22% respondents are in the old age group. The mean and standard	
141	deviation of the respondents is about 42.57 and 9.27 (Uddin et al. 2017).	Comment [s44]: et al.,
142	1.2 Level of education of the respondents	Comment [s45]: E
143	The education scores of the respondents ranged from 0-17 with a mean and standard	Comment [s46]: R
144	deviation of 6.81 and 3.63, respectively. On the basis of education the respondents are	
145	classified into five categories shown in Table 1. It was revealed that the highest portion of the	
146	respondents (49.5%) has achieved secondary level of education followed by primary level	
147	(25.3%), higher secondary level (11%). The lowest number of respondents (2.2%) were	
148	graduate and above. Only 12% of the respondents were illiterate.	
149		
150	1.3 Family size	Comment [s47]: S
151	Data presented in the table 1 indicate that most of the respondent (78.02%) belonged to	Comment [s48]: T
152	medium sized family category followed by small size family (18.68%) while only 3.30%	
153	belong to large family sized category. The mean and standard deviation of the family size	
154	6.00 and 1.51 respectively (HIES, 2010)	Comment [s49]: ,
155	1.4 Experience in farming	Comment [s50]: F
156	To measure the experience, the duration of involvement of the farmers in agriculture was	
157	considered. The mean and standard deviation of the experience in farming is 18.98 years and	
158	8.42, respectively. Based on the experience in agriculture, the farmers were grouped into	
159	different categories as shown in the table 1.	Comment [s51]: T

It was found that the majority (47%) of the respondents had medium experienced and a very 160 few (18%) was low experienced. And the rest (35%) of the respondents was high 161 162 experienced. So, the information seeking tendency of the farmers seem to be low to medium and similar trend founded by Miah et al. (2016). 163 Comment [s52]: et al., 1.5 Annual income of the farmers 164 165 On the basis of the family income the respondents, family was classified into three categories as shown in table 1. It was found that majority (58.24%) of the respondents were in income 166 Comment [s53]: T range of Tk. 50001-100000 followed by (17.58%) in the income range of Tk. <50000 and the 167 least (24.18%) of the respondents were in the income range of Tk. <100000. Findings 168 indicate that lower income group peoples are engaged in agriculture for increasing their 169 income. The similar findings found in the study conducted by Hag (2016). 170 171 172 1.6 Farm size of the respondents Comment [s54]: S Comment [s55]: R 173 The mean of farm size was 18 with the standard deviation was 17.71. On the basis of their 174 family size, the farmers were classified into five categories as shown in Table 1. Data 175 presented in table 1 reveal that majority (45.05%) of the respondent was small farmers, 32% 176 marginal farmers, 12% medium farmers and 5 % was landless. Data also revealed that 177 majority of the farmers of the study area had marginal to small farmers. 178 1.7 Extension media contact (year) Respondents use various information sources and media to a different extent in order to 179 180 receive agricultural information. The average and standard deviation of extension media 181 contact score was 9.42 and 5.44. Based on computed extension media contact score, the 182 respondent were classified into three categories as shown in table 1. So, the information Comment [s56]: ⊺ 183 seeking tendency of the farmers seem to be low to medium and similar trend founded by 184 Miah et al. (2016). Data presented in the table 1 shows that majority of the respondents Comment [s57]: et al.,

185	(70.33%) had low media contact as compared to medium contact (27.47%) and had high		
186	contact (2.20%). Respondent's exposure to a variety of information sources usually guides		
187	them to identify problems in vegetable cultivation and how to solve the identified problems.		
188	1.8 Organizational participation		
189	Depending on the individual organizational participation scores, the respondents were		
190	grouped into the following categories as shown in table 1. It is revealed from the present		Comment [s58]: T
191	study that majority of the respondents (76.93%) have low organization participation followed		
192	by medium participation (23.08%). The mean and standard deviation of organization		
193	participation was 1.97 and 2.31 respectively.		Comment [s59]: ,
194			
195	1.9 Cosmopoliteness		
196	The mean and standard deviation of cosmopoliteness scores of the respondents was 5.64 and		
197	2.19, respectively. Based on Cosmo-politeness score, a respondent have been classified into		
198	three categories as shown in the table 1. Data presented in Table 1 reveal that majority (58%)		Comment [s60]: T
199	of the respondents had low cosmopoliteness. Only 3% of the respondents are highly		
200	cosmopolite while 39% of the respondents had medium cosmopoliteness.		
201	1.10 Use of Conservation Agriculture (CA) for vegetable cultivation	< []	Comment [s61]: V
202	Based on use of conservation agriculture, farmers were classified into two categories as	_	Comment [s62]: C
203	shown in table 1. About 90% of the people use conservation agriculture for vegetable		Comment [s63]: T
204	cultivation. Only 10% of the respondents cannot use conservation agriculture for vegetable		
205	cultivation. The mean and standard deviation of the use of conservation agriculture was 45.50		
206	and 51.61. It seems that worldwide the practice of CA was on the lower side of around 10		
207	per cent farmers only (Willer et al., 2008).		Comment [s64]: et al.,
208	1.11 Use of <mark>f</mark> ertilizers and <mark>m</mark> anures	<	Comment [s65]: F
			Comment [s66]: M

209	It was observed that most of the respondents used fertilizer and manures in their vegetables	
210	cultivation. Among 91 respondents, 87 respondents cited that they used urea while 87, 87, 84,	
211	43, 24, 13 respondents used manures, TSP, MoP, zypsum, zinc and boron, respectively. The	
212	mean and standard deviation of fertilizers and manures used was 60.71 and 33.05 (Table 2)	
213	1.12 Intercultural operation	Comment [s67]: 0
214	Intercultural operations followed by the respondents are shown in the table 3. Among 91	Comment [s68]: Table
215	respondents, 78 respondents cited that they used weeding while 77, 14, 75, 65, 67, 42, 34, 27	
216	and 6 respondents used irrigation, mulching, spading, disease control, insect control,	
217	thinning, pruning, inter-cropping and other intercultural operation for conservation	
218	agriculture. For traditional agriculture (TA) 84 respondents used weeding while 84, 61, 83,	
219	82, 82, 52, 53, 41 and 11 respondents used irrigation, mulching, spading, disease control,	
220	insect control, thinning, pruning, inter-cropping and other intercultural operation. The mean	
221	of intercultural operation for CA and TA was 48.4 and 63.3. The standard deviation of both	
222	CA and TA was 27.48 and 24.53.	
223	1.13 Disease Infestation in the Vegetables Cultivation	
224	The disease infested in vegetable cultivation of the study area has been presented in table 4. It	Comment [s69]: T
225	was revealed from the results of the present study that leaf rot is the most occurring disease in	
226	the vegetables cultivation cited by 43 respondents out of 91 respondents followed by root rot	
227	(29), fruit rot (31), brown spot (11), fungi (27), black spot (6) and late blight (13).	
228	1.14 Insects infestation in vegetables cultivation	Comment [s70]:
229	The occurrence of insect infestation is shown in the table 5. Among 91 respondents, 45	Comment [s71]: V Comment [s72]: C
230	respondents cited that most vegetables were infested greatly by rice brown plant hopper	Comment [s73]: T
231	(current poka) followed by stem borer (31), dragon and damsel fly (3), aphid (22), termite	
232	(17) and fruit borer (11).	Commant (-74), c
233	2. Problem confrontation related to agriculture	Comment [s74]: C Comment [s75]: R
_30		Comment [s76]: A
	9	

The respondents gave their opinion about different problems confronted by them. The study 234 revealed that the main problems of agriculture in Khulna region are the salinity (61.54%), 235 lack of activities of extension workers (49.45%), high incidence of insect (29.67%), lack of 236 knowledge (28.57), natural calamities (16.48%) etc. The list of problems and the severity 237 238 have been On the basis of problem confrontation score the respondents were classified into three 239 categories which are shown in table 7. Comment [s77]: T 240 241 It was revealed from the study that total 59 (64.84%) of the respondents were under medium 242 problem confrontation, 21.98% were under low problem confrontation and 13.19% were under high problem confrontation. The respondents gave their opinion about the probable 243 solution of the problems which were ensuring adequate seed and seedlings, ensuring 244 sufficient amount of insecticides and pesticides at reasonable price, ensuring high quality 245 fertilizers, increase irrigation facilities etc. The score of problem confrontation with a mean 246 of 30.33 and having standard deviation 25.15. 247 3. Cropping pattern in the Khulna region following Conservation Agriculture 248 This section was measured by four different types of study area such as high land area, 249 medium high land area, medium low land area and low land area. Among 91 respondents, 250 about 85.71% of the respondents produce crops in medium high land, 10.99% and 3.30% 251 respondents produce crops in high and medium low land. The low land in the Khulna region 252 253 was used for shrimp farming. In this four types land, crops are produce three season in a year Kharif I, Kharif II and Robi season. 254 255 3.1 High land Comment [s78]: L

Among 91 respondents, only 10 respondents cited that they produce crops on high land

topography. During Kharif I season, 100% (N=10) of the respondents cultivate paddy

256

258	followed by 20% brinjal, 10% cultivate papaya, pointed gourd and turmeric. The crop			
259	rotation used in high land ranged from 1-10 with a mean and standard deviation 2.6 and 3.05,			
260	respectively. Based on land topography, crops were cultivated in kharif I season as shown in			
261	table 8.			
262	In kharif II season, 40% (N=10) respondents cultivate bitter gourd where as 30% cultivate			
263	brinjal and 10% cultivate chilli. The mean and standard deviation found in kharif II season			
264	was 2.67 and 1.53. Based on land topography, crops in Kharif II season are shown in table 8.			
265	Data presented in the table 10 revealed that the Robi crops cultivated by the respondents			
266	ranged from 1-10 with a mean and standard deviation of 2.55 and 2.77. Among 10			
267	respondents, 100% (N=10) of the respondents cultivate tomato in robi season followed by			
268	20% cultivate red amaranth and chilli, 50% cultivate aus paddy, 30% cultivate cabbage and			
269	10% cultivate yard long bean, broad bean, pumpkin, bottle gourd, mustard and cauliflower in			
270	high land. Based on land topography, crops were cultivated in Robi season as shown in table		Comment [s79]: ⊤	
271	8.			
272	3.2 Medium <mark>h</mark> igh land	<	Comment [s80]: H	
273	It was observed that majority of the respondents (N=78) used medium high land for	71	Comment [s81]: L	
274	cultivation of crops. Among the 78 respondents, 32 respondents cultivate paddy while 13, 10,			
275	8, 6, 5, 4, 3, 2 and 1 respondents cultivate brinjal, turmeric, lady's finger, jute, Indian spinach,			
276	wheat, cucumber, pumpkin etc. respectively during kharif I season on medium high land.			
277	Data presented in the table 4 indicate that the Kharif I crops cultivated by the respondents			
278	ranged from 1-32 with a mean and standard deviation of 6.06 and 7.72. Based on land			
279	topography, crops were cultivated in Kharif I season as shown in table 9.		Comment [s82]: ⊤	
280	At the time of Kharif II season, almost 32 respondents cultivate dhan (paddy) followed by 11			
281	respondents cultivate BRRI Dhan-28, 7 respondents cultivate indian spinach. The data table8	(Comment [s83]: ⊤	

indicate the crops that are cultivated by the respondents in Kharif II season on medium high 282 land with a mean and standard deviation of 5.83 and 8.81. 283 284 During Robi season, farmers were cultivating winter crops for local demand. Among 78 respondents, about 43.59% respondents cultivate tomato, 29.48% produce red amaranth, 285 286 33.33% produce chilli, 26.92% produce cauliflower, 28.21% produce potato, 21.79% produce 287 cauliflower etc. Data presented in the table 9 indicate the crops that were cultivated in robi season on medium high land topography. 288 3.3 Medium low land 289 Comment [s84]: L Comment [s85]: L 290 Among 91 respondent, it was observed that only three respondents (N=3) used medium low 291 land for cultivation of crops. Among 3 respondents, 100% (N=3) of the respondents cultivate paddy in kharif I season. They also produce indian spinach, banana, dhan (aus), lady's finger 292 in kharif I season. Data presented in the table 10 indicate that the crops cultivated by the 293 Comment [s86]: T respondents ranged from 1-3 with a mean and standard deviation of 1.6 and 0.89. 294 In kharif II season, 2 respondents cultivate aman-30, 1 respondent cultivate BRRI dhan-28 295 and 1 respondent cultivate lady's finger. Data presented in the table 10 indicate that the crops 296 cultivated by the respondents ranged from 1-3 with a mean and standard deviation of 1.33 297 and 0.58. 298 During robi season, majority (100%) of the respondents cultivate tomato, potato followed by 299 spinach (66.67%), red amaranth (66.67%) and mustard (33.33%) respectively. Based on 300 Comment [s87]: M 301 medium low land topography, crops were cultivated in Robi season as shown in table 10. Comment [s88]: T 302 IV. Conclusion 303 304 Findings of the study and the logical interoperations of their meaning in the light of other 305 relevant facts prompted to draw the conclusions that the highest portion of the farmers was

middle aged having small family and small farm sized with low cosmopoliteness and low 306 organization participation. About half of the respondents possessed with secondary level of 307 education. Majority of the respondents were in high income range and medium experience in 308 farming. Maximum number of the respondents uses fertilizers and manure and different 309 310 intercultural operations and takes control measures against disease and insect infestation. 311 Different cropping pattern found in the study areas like high land, medium high land, medium low land and low land. Most of the respondents were cultivated their land on medium high 312 land topography. The vital problems found in the study area in case of conservation 313 agriculture were salinity, lack of knowledge, lack of seed, high price of seed, lack of 314 fertilizers etc. and farmers gave their opinion to solve those problems. 315
