

“Experimental Investigations Problems of Drift in Aerial Spraying”

Abstract

Agricultural and forestry requirements for agricultural aviation related to spread of fertilizers, crop protection and protection against pests in forestry are presented. Some mathematical models describing aerial spraying and the distribution of liquid droplets on a target are discussed, but the main problems presented on this paper are results of experimental investigations in field of “the drift in aerial spraying”

Key words: agricultural aviation, aerial spraying, drift

1. List of major symbols:

19	a	[ha/m ²]	- coefficient
20	d	[μm]	- droplet diameter (average, d _V , d _{MV} ...)
21	d _S	[μm]	- trace droplet diameter
22	d _{VM}	[μm]	- volume meridian diameter
23	h	[m]	- aircraft altitude
24	g	[number/cm ²]	- spray density
25	l	[m]	- wingspan
26	m	[kg]	- mass
27	m _S	[dcm ³ /s]	- sedimentation flow rate
28	p	[N/m ²]	- wing loading
29	A	[m ²]	- area
30	B	[m]	- working swath
31	D _P	[dcm ³ /ha]	- field dose
32	D _T	[dcm ³ /ha]	- technical dose
33	F		- agent
34	I		- turbulence intensity
35	W	[dcm ³ /s]	- flow rate
36	V _I	[m/s]	- operating speed
37	V _S	[m/s]	- sedimentation velocity
38	V _W	[m/s]	- average wind velocity
39	T	[K]	- temperature

40	U_K	- constructional design
41	Z	- drift
42	α, β, φ	- inclination, rolling, yawing
43	ψ	- relative humidity
44	λ	- aspect ratio

45

46

47

48

1. The Bio-aeronautics

49

50

The name was given by Southwell (1975), and the definition is „*application of different types of aviation to the development of useful living organisms on the Earth*”. As the origin of this field of aviation is considered a patent received by Alfred Zimmermann, a forester from Detershagen (D) on 21th of March 1911. The patent belongs to the problem of *Lymantria Monacha* L control in Germany forests.

54

55

1.1. The possibilities of the Bio-aeronautics.

56

In spite of its small actual operating range on the World scale, the bio-aeronautics can play very important role to the improvement of the nutritional World situation especially for countries of Asia, Africa, South and Central America.[3]. In those regions a feeble infrastructure, a very poor agricultural mechanization and a shortage of specialists cause that in some fields of activities the only practical alternative is the bio-aeronautics.

61

62

1.2. The main fields of activity of bio-aeronautics are:

63

- control of human and animal disease vectors (tsetse fly, onchocerciasis)
- control of mass infestations (Locust, Quelea)
- plan protection treatment (cereals, cotton, rice, maize, root crops and others)
- application of fertilizers
- reclaiming, erosion control, ground stabilisation
- delivery of agricultural and others products
- health control

68

69

Parallel with test of new apparatus, new aircrafts for use in agriculture and forestry, took place the analyse some most important problems of aerial treatment concern:

72

73

1.3. Treatments.

74

- The main problems of aerial treatment and wisies by agricultural and forestry specialist are:

75

Treatments must do in time (agricultural time)

76

- Minimalizing the risk of environmental pollution, problem of drift

77

- The distribution quality of the sprayed /spread products

78

- Effect of economy. (B – max for data CV)

79

80

1.4. The agricultural times.

81

Jest to przedział czasowy, w którym powinien być wykonany zabieg ochrony, nawożenia, inny, zapewniający najwyższą skuteczność stosowanego środka. Dla ochrony, będzie to skuteczność biologiczna.

84

85

1.5. Quality of distribution.

86 Rozumie się przez to wykonanie zabiegu w terminie agrotechnicznym, przy określonych
87 warunkach meteorologicznych, przyjętą dawką i formulacją środka. Stosowana dawka winna być
88 rozłożona na uprawie (glebie) z określoną równomiernością - ustalonym współczynnikiem zmienności.
89 The quality of distribution, as well as the elements induced drift are connected with: disturbances of the
90 flow field around the flying aircraft, especially the vortex sheets travelling from the wings and the
91 disturbances given by the propeller. This effects is mainly join with the construction design of airplanes.
92 Uwzględnia się również wpływ bliskości ziemi i charakter pokrycia.

93 94 95 1.6. Working width (B)

96 Przyjęta w zabiegu szerokość robocza zależna od constructional design of the agricultural
97 aviation, typu aparatury, rozprzestrzenianego środka. Przyjmuje się jej wartość w zabiegach
98 opryskiwania: atomizers 35 m – 40 m, jet nozzles 20 m – 30 m. For spreading: 20 m – 30 m. depends on
99 materials. Make an assumption for the coefficient of variation of the order 20%,for receive
100 magnification of (B), were experimental investigations, wing tips. [11],[17]

101 102 1.6.Problem od drift.

103 It is “unintentional effect of treatment cause movement of chemicals outside of the targed. For
104 liquids the movement has direct and indirect form. Direct one belongs to drift of spray in all form of state
105 (particles as a result of evaporation of droplets, liquids, and vapour), Indirect – movement with wind
106 vapour of settled droplets and particles after evaporation of liquids”. [2],[16],[20],[25],[26],[27],[29]

107 Induced drift:

- 109 • Meteorological conditions in terrain of treatment
- 110 • Disturbances of velocity field caused by flaying aircraft

111 Physical characteristics of dispersed agent. Liquid: droplets size and formulation.

112 Solids: granulation, dusty agents, crystalline agents, taking their humidity into account

113 Terrain of treatment

- 114 • Flight parameters and quality of a pilot.

115 Negative effects of spray drift:

- 116 • The loss of chemicals
- 117 • The decrease of efficiency of pesticides on the target area
- 118 • Other losses related to the damage or pollution of adjacent crops, water, urban area, gardens
- 119 • Contamination of environment with a possibility of unpredictable secondary effects
120 (residues, interaction, etc.)
- 121 • Sociological factor, understood as non-scientific media trend of criticizing chemical plant
122 protection treatments leading to baseless social dislike for those, mainly for aerial spray treatments.

123 The above-mentioned have resulted in the European Union issuing a peculiar document called
124 Directive 2009/128/WE of the European Parliament and of the Council of 21 October 2009. Official
125 Journal of the European Union L 309 of 24 November 2009. In the document in Chapter IV, Article 9,
126 Paragraph 1 reads:

127 1.Member States shall ensure that aerial spraying is **prohibited**.

128 2.By way of derogation from paragraph 1 aerial spraying may only by allowed in special cases provided
129 the following conditions are met (points a through f of the aforementioned document).

130 131 2.Theoretical analyses 132

133 Generally, from mathematical point of view, the four factors have been researched for over 60
134 years both theoretically and experimentally. The subject bibliography is over 500 titles long, although, it
135 is often contributory literature [6]. To recapitulate, the above factors can be presented as four functions
136 that mutually influence each other. They are bound as follows:

137

$$138 \quad K = f_1(U_k, \lambda, p, l) \quad (1)$$

$$139 \quad L = f_2(V_r, h, \alpha, \beta, \phi) \quad (2)$$

$$140 \quad M = f_3(V_w, T, T_r, \psi) \quad (3)$$

$$141 \quad C = f_4(m, d, F, A) \quad (4)$$

142 where:

143 K – construction design

144 L – flight parameters

145 M – meteorological conditions

146 C – propagation of agents

147

148 There are two types of methods that illustrate the motion and distribution of droplets. Methods
149 that do not account for the influence of disturbances in the velocity field behind the aircraft on droplet
150 motion and distribution. Referred “free models”. Presented by: [1],[4],[7],[8],[13],[16],[18],[21],[23].

151

152 2.1. Free models.

153 1. In a spray cloud, droplets concentration have Gaussian distribution with standard deviation σ_y along the
154 y-axis in the direction of the wind and σ_z – relative to the vertical z – axis

155 2. The cloud becomes dispersed due to sedimentation, turbulence and wind motion.

156 3. Droplets are small, implying that sedimentation velocity is low

157 4. Droplets evaporation rates have been taken into account

158 5. Average wind speed and coefficient of turbulent diffusion remain constants with change in height.

159 6. All droplets leave the cloud when it reaches the top of the crop and penetrates it.

160 Use the CSANADY^S [5] concentration function, is possible to receive the dose distribution in (y,z)
161 direction.

162

163 2.2. Bound models.

164 Methods that do account for above factor as well as other parameters. Referred “bound models”.
165 Presented by the first Reed W.H. in NACA Report 1954 [14] and [9],[10],[12],[13],[21],[22],[26],[27].

166 Were also many papers presented this model, but Pietruszka [12] and AGDISP models [2],[19],
167 [24],[25] look the most interesting.

168 The model propose by Pietruszka [12] take in to account;

169 1. The wing wake is modelled by inviscid and incompressible flow of 22 vortex line

170 2. Vortex displacement from propeller axis and deformation of the propeller wake due to wing
171 interference were taken into account

172 3. additionally the velocity field is modified by the influence of ground proximity

173 4. droplets evaporation have been taken in analyse

174 5. the logarithmic wind velocity profile near the ground is determined by the height of crop plants.

175 The Agriculture Dispersal (AGDISP). [2],[19],[24],[25], is popular and is the currently Nord
176 American Standard. But in this model are some simplifications:

177 1. the wing wake is modelled by only one vortex line

178 2. the propeller wake has too big simplification

179 3. is the same problem with equations of circulation especially for helicopters

180 Interesting is also last Sereodyn [21] analysis.

3.Experimental investigation

3.1.The method is in “*The Methods of the Test Agricultural Aircrafts and they Apparatus*” [14], presented in Russian language. Methods are for certification of Agricultural Aircrafts for treatments in agriculture, forestry and other branches of national economy. This methods was “*Acceptance for use*” by: , Bulgaria, Cech-Slovakia, DDR, Hungarian, Poland, USSR.

3.2. The trials were made agree with [15]:

on a former airfield in Gryźliny near Olsztyn, and in lover experimental range in Mielec.

In Gryźliny.

Its surface is about 150 hectares and covered with 0.1+0.15m tall grass.

3.3. Objects: The airplane An -2R, produced in Polish Aviation Factory - Mielec.

The helicopter Mi -2R, produced in Polish Aviation Factory - Świdnik.

- There are 3 to 5 repetitions of the test
- The test took place between 5 to 8 am. and from 5 to 8 pm., for the better meteorological condition

3.5. Measure line and samplers

Thirty metres from the zero point of the measure line, a direction line perpendicular to it was determined for the agricultural aircraft flight. This was marked with markers which informed the pilot where to switch the apparatus on and off. This distance was equivalent to 5s of agricultural aircraft flight before and 5s of the flight after the measure line. Each flight was conducted at a speed and altitude accepted in research programmes, and was rectilinear without rolling or yawing. The correctness and height of each flight were controlled by the pilot. Moreover, they were registered by two coupled cameras, perpendicular to each other’s Close to the measure line, at a height of two metres,

222 meteorological conditions during the test were registered. The following data were measured and
 223 registered: temperature, ΔT - the difference of temperatures on dry-bulb and wet-bulb thermometers
 224 (Assmann's method), wind velocity (gust velocity included) and direction of the wind. Figure 1 shows the
 225 scheme of the measure line.

226 Fig. 1. Scheme of measure line (1-measure line, 2- flight path, 3- mass samplers, 4- droplet
 227 samplers,
 228 5- masts, 6- measurements of meteorological parameters, 7- camera, 8- markers).

231 After the flight and subsidence of the spray cloud (after 8+10 minutes), the samples were
 232 collected and replaced by new ones. Following the direction of the wind, an 800 metre measure line was
 233 established.

235 The line was composed form the following samplers:

236 1. to measure mass distribution:

237 cellophane samplers (0.01m^2 each) were distributed horizontally at grass level (0.20m), every two
 238 metres over a distance of 200 metres for the plane and 140 metres for the helicopter;

239 2. to measure liquid dispersion:

240 dispersion in this case is understood as the number of droplets and the structure of their spectrum
 241 obtained from the surface of samplers. Samplers were microfilm negative tapes marked and
 242 plasticized with $6\mu\text{m}$ of thick mineral oil. This tape was then cut and framed for slides. The
 243 surface of the samplers at $4.05 \cdot 10^{-4}\text{m}^2$ (4.05cm^2) and $7.03 \cdot 10^{-4}\text{m}^2$ (7.03cm^2). This method was
 244 patent.

245 The above-mentioned samplers were placed: on stands (0.20m tall) and distributed horizontally, at an
 246 angle of 45° and vertically.

248 The stands were distributed:

249	every 5m	from 0+100m,
250	every 10m	from 100+200m,
251	every 20m	from 200+300m
252	every 50m	from 300+500m,
253	every 100m	from 500+ 800m.

254 The stands with samplers were placed in two rows. One row had 9 samplers (three in each
 255 exposure) which were replaced after every test flight. The other row had 3 samplers (one in each
 256 exposure) which were replaced after each series of three or five test flights agricultural aircraft.
 257 8 metre-tall masts, distributed 100m, 300m and 500m from the beginning of the measure line. The
 258 samplers on the masts were distributed every one metre, one vertically and one horizontally along
 259 the whole mast length. In opinion of specialists mast's tall have to be at list 11 m– 13 m., but
 260 was too difficult to did it.

261 4. Analysis of results

262
 263 In this paper are presented results of experimental investigation only of An-2R. Results of the test
 264 of Mi-2R are in [20].

265 Mass distribution was analysed using the colorimetric method on a spectral colorimeter with
 266 a length range of $\lambda = 580\text{nm}$. After recalculations, the distribution was presented in the form of dose
 267 distribution in a distance function, $D_p = f(y)$, for each performed flight, mean value and distribution
 268 uniformity analysis. The tests of droplets were conducted using indirect methods, by measuring
 269 fixed, coloured traces. The size, surface density (i.e. spray density) and the structure of the droplet
 270 spectrum were determined on a computer image analyser, based on fixed coloured droplet traces. The
 271 traces were grouped into ranges, according to trace sizes. The collection of droplet traces, arranged
 272 according to droplet diameters, was converted into a collection of droplets based on equations presented
 273 in Table 3.

274
 275 Table. 3. Scaling equations.

No.	Solution	Functional relations $d = f(ds)$	Diameter
1	N	$d = -0.0087 + 0.54155ds - 0.13643ds^2 + 0.01459ds^3$	> 0-1.7mm
2	M	$d = 100.707 + 0.56334ds$	> 0- 600mm

277
 278 The results are recorded in the form of a distributive ordered series from each measuring point,
 279 and sum of the number of droplets in classes from the measure line or a pan of it, e.g. the masts. These
 280 results are presented as size, surface density (i.e. spray density), average diameters (arithmetic and
 281 volumetric), and medians (quantitative and volumetric). Cumulative quantitative and volumetric
 282 distributions of liquids, which is the basic information about the spectrum structure, are presented
 283 graphically.

284 Analysis determined:

- 285 1. the change of dose in relation to drift distance – y direction, and average doses for airborne crop
 286 protection treatment working breadth ($B=30\text{m}$),
- 287 2. the distribution of surface spray density along an 800m strip,
- 288 3. the structure of the droplet spectrum along the 800m strip (i.e. the change of average droplet
 289 diameter in relation to drift distance),
- 290 4. droplets evaporation and sendimentation in drift distance
- 291 5. airborne movements of droplets clout received on masts

292 4.1. The distribution of mas

293
 294 The mass distribution of a spray in the case of a cross-wind is characterized by asymmetry, the shift
 295 of the centre of mass with the wind in relation to an aircraft flight direction, and a large spray area with a
 296 low dose. The average mass distribution from three flights for the technical dose of $D_r = 48.35\text{dm}^3/\text{ha}$ is
 297 presented in figure 2.
 298

305
306
307
308

309 Fig. 2. Example of mass distribution (— experiment, - - theory) [18]. Parameters: D
310 $=48.35\text{dm}^3/\text{ha}$; $V_r = 44.4\text{m/s}$; $V_w=4.5\text{m/s}$; $h=4.5\text{m}$; $d_v= 187\mu\text{m}$, $I = 0.1$

311
312
313
314

To present drift, mass distribution can be quantized by relating it to a generally accepted working
breadth $B=30\text{m}$, used in plant protection treatments performed by aircraft.

Average values for sprays by atomizers and pressure nozzles are presented in figure 3.

321

322

323

324

325

326

Fig.3. Percentage mass distribution at 30m intervals (a - atomizers, 2% water solution of nigrosine, b-atomizers, 30% urea solution in 2% water solution of nigrosine, c- pressure nozzles, 2% water solution of nigrosine, d- pressure nozzles, 30% urea solution in 2% water solution of nigrosine)

327 A higher settlement in a working breadth of 30m occurs when droplet diameters are larger and
 328 when urea is applied as a weighting agent in liquids.
 329 Because of threats to neighbouring crops, fauna, water regions and urban areas, it is important to
 330 define a share of drifted dose in relation to the applied dose (i.e. to define a technical dose in the
 331 function of drift distance).

332 For atomizers, these relationships are the following:
 333
$$\check{D} = 0.1045 - 0.0211 \ln y \quad (5)$$

 334 with correlation coefficient: $r = -0.9511$, for $15 \text{ m} \leq y \leq$
 335 140 m .

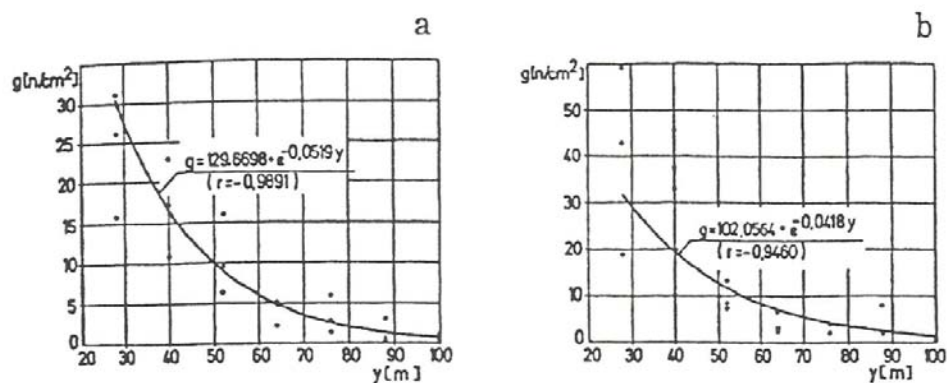

336 For pressure nozzles, these relationships are:
 337
$$\check{D} = 0.4633e^{-0.0246y} \quad (6)$$

 338 with correlation coefficient: $r = 0.9792$ for $15 \text{ m} \leq y \leq$
 339 210 m .

344 4.2. The settlement of droplets

345 Examination of settled droplets was based on the analysis of samplers placed along the
 346 800 metre measure line. The distribution of samplers (discussed in methodology), made analysis
 347 possible not only for horizontal samplers, but also for skew and vertical ones. The breadth of the
 348 droplet settlement strip was defined as $y \leq 500 \text{ m}$. The droplets of urea solution achieved a wider
 349 breadth than the nigrosine solution droplets. This phenomenon is connected with lower degree
 350 of evaporation and a higher rate of sedimentation for the urea solution droplets. In the
 351 experiment there was a discrepancy in the breadth of settlement in relation to atomizers and
 352 pressure nozzles. This discrepancy can be explained by disturbances of the velocity field behind
 353 flying aircraft and by turbulence. The settlement of droplets sprayed by atomizers on horizontal
 354 samplers is characterized by a very low density and by the shift of spray over significant
 355 distances. A higher surface density of spray was obtained for the urea solution than for the
 356 nigrosine solution, due to the above-mentioned factors.

357 The distribution of spray surface density for pressure nozzles has the character of mass
 358 distribution. The spray density and the regression function for pressure nozzles
 359 are presented in figures 4a and 4b.

360

4.3. Droplets evaporation and sedimentation

The droplets, drifting with the wind, undergo a segregation and a process of evaporation. This is why the average diameter of settled droplets in the function of drift distance was examined. The analysis included all examined spraying sets and both model liquids. The parameters were the relative volumetric diameter, and the time after which a droplet settled. The results of the analysis can be presented as the general relationship: The values of coefficients are presented in table 4.

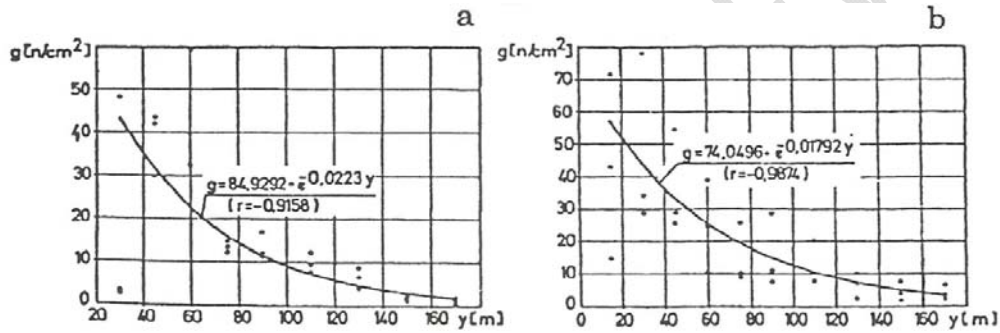

372

$$d_v = A t^{A1} \quad (t = y/V_W)$$

387
388

389

390

391

392

393 From the data in table 4 it follows that better compatibility of function occurred for pressure
394 nozzles producing larger droplets. Smaller droplets are significantly influenced by the field of
395 velocity disturbances behind a flying aircraft. This is confirmed by better repeatability for small
396 droplets calculated for distances 3-4 times longer than wingspan. In this area the field of velocity
397 disturbances is already disappearing.

398 4.4. Airborne droplets

399 The shift of spray in an 8-metre layer of air was defined by analysing droplets settled on samplers
400 which were placed vertically on the masts. Sediment of droplets on these samplers, of the small angle of
401 elevation, best characterizes drifted droplets. The densities of spray for all sets and model liquids are
402 presented in figure 6a.

437
438

The second experiment took place in Polish Aircraft Plant (PZL) in Mielec. They carried out a crop dusting experiment with the involvement of the M18 "Dromader" airplane equipped with jet type nozzles. Flying height was 4 m and flight speed was $46.4 \text{ m}\cdot\text{s}^{-1}$ along the wind axis and against the wind. Liquid flow rate was $7.1 \text{ dm}^3\cdot\text{s}^{-1}$ and the volume-median droplet diameter was $d_{MV} = 215 \text{ }\mu\text{m}$. The modeled liquid was 1% aqueous solution of nigrosine. Every test was performed in 3 replications. Droplet evaporation rates were very low due to high relative humidity of 98%. Crosswind speed was $0.2 \text{ m}\cdot\text{s}^{-1}$.

439
440
441
442
443
444

Results are in Fig.7.

Fig.7. Lateral distribution of 1% nigrosine aqueous solution determined theoretically and experimentally [12], compare with proposed by [26].

5. Estimation of measuring error

445
446
447
448
449
450
451
452
453
454
455
456

Here is a short analyse od errors. In the above-mentioned experiments treble averaging of samples was applied. To define if this multiplication factor is enough, it was assumed that the averages from 3 groups of measurements and variations of these groups are equal to each other. The alternative hypothesis, that not all of them are equal to each other, was also assumed. To verify these two hypotheses, test F (Snedecor and Bartlett's (f)) was applied, with critical value on significance level $\alpha=0.01$. The values of test statistics were defined. The equality of group variations was also tested.

For tests performed with W 17-4 and W7-2 sprayers for both model liquids, there is no basis to reject the hypothesis of average equalities and group variations.

For atomizers, the testing showed that the averages vary significantly, relative values do not differ significantly and they were used in this form for further analyses. Errors of other measurements were also estimated (dosage, rate-of-flow and droplet size included).

457

6. Drift

458
459

The amount of drifted liquid is the difference between a technical dose and the field dose¹. This difference can be presented as the following relative relationship:

460

$$Z = \frac{D_T - D_P}{D_T} = 1 - \frac{D_P}{D_T} \quad (8)$$

461

where: $D_T = a \frac{W}{B} V_r$ a – coefficient 10^4 [ha/m²] (9)

462

After the analysis of many parameters (technical dose and average volumetric diameter of droplets included), a relative amount of drift was related to a volume diameter d_{VM} median which is an essential measure of spray structure. On the basis of research these relationships (for 2% water solution of nigrosine and 30% urea solution in 2% water solution of nigrosine) are as follows:

466

$$Z = 134.9377 d_{VM}^{-1.0757} \quad (10)$$

467

with correlation coefficient: $r = 0.8690$ for diameter range $100 \mu m \leq d_{VM} \leq 250 \mu m$

469

$$Z = 2.3269 e^{-0.0047 d_{VM}}$$

470

With correlation coefficient: $r = -0.8470$ for diameter range $200 \mu m \leq d_{VM} \leq 400 \mu m$

471

In the case of a global analysis of air drift, the following equation can be use :

472

$$Z = 13.5324 d_{VM}^{-0.5955} \quad (11)$$

475

with correlation coefficient: $r = -0.6481$ for diameter range $100 \mu m \leq d_{VM} \leq 400 \mu m$

476

477

Is possible to compare this results with Zemp [29] equations :

478

for airborne spraying: $Z = 1.48 d_{VM}^{-0.01}$ (12)

480

for sprays with ground equipment $Z = 1.86 d_{VM}^{-0.01}$ (13)

481

482

The results of analyses are presented in fig.8.

483

484

485

The results of analyses are presented in figure 8.

486

From tests carried out here it follows that smaller droplets drift more than Zemp's equations state.

487

488

Environmental protection, it essential to define the lateral distribution of drifted liquid. The drift may be divided into two processes:

489

490

491

1.in relation to the movement of droplets which settle on crop within the tested area.

492

493

and

494

2.in relation to a spray cloud which moves with the wind in the near-ground air layer (the spray cloud

495

496

may be measured by the structure of spray which settles on the masts Fig.8. Drift analysis

497

498

499

Field dose is the mass or amount of liquid which settled on samplers in relation to samplers sizes, with in the working breadth and with the assumption that a marker in model liquid does not evaporate.

500

501

502

9. Protection Zones

503

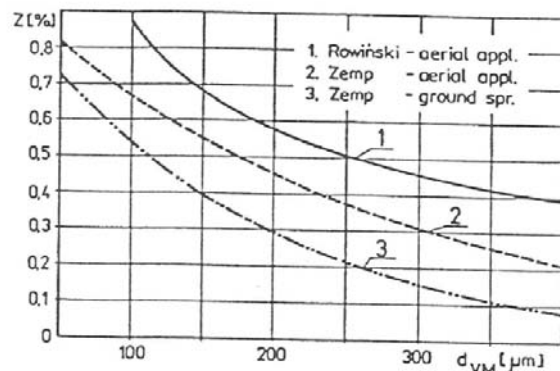

504

The results of the above experiments confirm the necessity of using protection zones for airborne plant protection treatments. These zones, according to the character of drift process, may be divided into two categories:

505

506

507

- 508 • the insulation zone (also called insulation strip), on the lee side of the treated area, where most of
- 509 the droplets settle, and
- 510 • the buffer zone, which provides protection from the negative effects of shift and settlement of a
- 511 spray cloud in the near-ground air layer.

512 The sum of these two zones constitutes the protection zone (see fig.9).

513 From the mass distribution analysis for both liquids applied it is possible to define the relative dose \check{D} (i.e.

514 the ratio of field dose to technical dose). Unlike equations 7 and 8, a real treatment was considered, where

515 distributions overlap with a shift equal to the applied working swath $B=30m$. The following results were

516 obtained:

517 for atomizers:

$$\check{D}=0.03032-0.0613 \ln y \quad (r = - 0.9932) \quad (14)$$

for pressure nozzles:

$$\check{D} = 0.9136 e^{-0.0273 y} \quad (r = - 0.9987) \quad (15)$$

518 Differentiating these equations, we obtain a measure of drop for a relative dose. These values are

519 the following:

520

521 for atomisers:

$$(d\check{D}/dy)_a = - 0.0613 * \ln y \quad (16)$$

522

523 for pressure nozzles:

$$(d\check{D}/dy)_p = - 0.025 e^{-0.0273y} \quad (17)$$

524

525 This means that during airborne treatment, in which pyrethroids are sprayed with atomizers, with

526 an acceptable level of dosage on a field's periphery,

527 e.g. $\check{D} = 4\%$, the area of drift will be $y \leq 73m$, and

528 insulation zone 43m (with a working breadth of 30

529 metres). Analogically, when herbicides are used in

530 airborne treatments, with an allowed dose on the

531 periphery of e.g. $\check{D} = 0.5\%$ the drift area is $y \leq 190m$,

532 and the insulation zone is 160m. These are also the

533 areas where droplets settle (see figures 6 and 7). The

534 area of a buffer zone can be estimated only on the

535 basis of dose which settles on vertical samplers on the

536 masts. This will depend on toxic and dynamic

537 properties of the applied pesticide, as well as on the

538 threat it poses to neighbouring areas.

541

Fig.9. The Protection zone

542

543 As mentioned above, a spraying conducted with atomizers settles at a distance of 300m in a dose in

544 relation to a technical dose $\check{D} = 0.047$, and at a distance of 500m for dose $\check{D} = 0.015$. Assuming a linear

545 distribution of a dose between the masts with the above-mentioned assumption that an allowed dose of

546 pyrethroid $\check{D} = 0.04$, it is possible to evaluate a drift distance $y=350m$. For pressure nozzles and the above

547 assumption $\check{D} = 0.005$, a drift distance is $y \leq 360m$. Buffer zones can be evaluated as 320m and 330m,

548 respectively, for working breadth $B=30m$. The above sizes of protection zones are extreme.

549 They were calculated for the application of herbicides and the threats related to them for the most
550 sensitive cultivated crops (i.e. lettuce and cucumbers). In the case of these plants, a relative dose of 0.1 %
551 to 0.5% can make it impossible for the crop to be sold [6].

552 Data on what doses responsible for crop losses are allowed or what pesticide residues are
553 acceptable make it possible to calculate protection zones (based on equations presented in this paper).
554 These zones will be much narrower for most insecticides and fungicides applied

555
556

557

10. Mass balance

558 The process of drift is an element of a broader
559 problem concerning the mass of an expanded
560 factor. Like in Thermodynamics Sankey' figure for
561 engines, the mass balance can be presented in
562 figure 10. In this balance (although it does not have
563 any direct influence on the mass), degradation of
564 chemicals (due to solar radiation) was also marked.
565 (evaporation). So far, broader research of the whole
566 process has not been available, and the- roses
567 aviation practice has been basically restricted to
568 biological effects. The balance presented here,
569 although it is – fall off from a plant extremely
570 difficult in experiments, will enable a complex
571 analysis of plant protection treatment efficiency, as
572 well as the negative effects of treatment on the
573 environment. It is interesting from agriculture
574 engineers to receive the total efficiency of our
575 treatments. (D_T /biological effect)

576

Fig.10.Mass balance

577

11. Conclusions

578
579

580 1. The Document of EU from 2009 year, forbidden use of airplanes in crop protection treatments,
581 and agreement is possible only in a particular situation. From that no reason to continue very
582 labour consuming and expensive, experimental investigation, in this field of knowledge. But if
583 will be continued should be based on a generally accepted, standard method which would
584 make it possible to compare results.

585 2. Still more attention should be payed to model research, mathematical model of drift
586 included, to recognize the physics of occurring processes. So far there have been too many
587 segment tests.

588 3. Application of pesticides require establishing protection zones (insulation and buffer
589 zones included) on the lee side. The breadth of these zones ranges from 50m to 60m
590 up to 330 m, depending on threats certain pesticides imply and the type of equipment.

591
592

593

594

595

12. Inference

596

597 The method was acknowledge by Ministry of Agriculture and Rural Development, The
598 Institute of Environmental Protection, The Forest Research Institute, as a better than EU
599 Directive to use airplanes in crop protection treatment and formally agree after analyse
600 presented the method to use treatments “Mospilan 20 SP” in insecticide control in forest.
