### **Characterization of Watershed and Soil Erosion Risk Assessment of Nun Basin Using *Remote Sensing and GIS*.**

**Comment [u1]:** Soil Risk Assessment of Nun Watershed using the Revised Soil Loss Equation model & GIS

This study aims to investigate the soil erosion from selected watershed from Dehradun area having hilly terrain and human's development activities. The remote sensing based model for determination quantity of soil eroded from watershed was decided to perform the estimations. The Nun river watershed was selected for study. From the estimated quantity of soil eroded we can predict the risk due degraded soil in terms of decreasing crop productivity. The present study assist to deciding the optimum land use for specific purpose at the Nun watershed in Deharadun, Uttarakhand. The major objective of the study is to assess the soil erosion risk in the study area.

#### **PHYSICAL SET-UP OF STUDY AREA**

##### **LOCATION-**

The study area is located in the Deharadun District of Uttarakhand, India. The district is situated in the foothills of Himalayas, in the north-west corner of Uttarakhand. The Nun watershed occupying an area of 4031ha It is situated at 30021'6''N to 30027'57''N latitude and 77059'9''E to 78025'67''E longitude was selected for the land evaluation analysis.

30

**PHYSIOGRAPHY :**

31

The watershed area is bordered by the lesser Himalayan ranges to the north and Siwalik to

32

the South. The Study area has different physiographic units like hills of varied slope

33

ranges, upper and lower piedmont. The northern part of study area consists of hills and

34

southern part is of piedmonts.

77 **DRAINAGE :**

78 Dehradun district is drained by Ganga, Yamuna and their tributeries. The two basins are  
79 separated by a ridge starting from Mussoorie and passing through Dehradaun. The easterly  
80 flowing river join river Ganga and westerly flowing rivers join river Yamuna. The Nun  
81 River flows from Hattipawan along the north south directions and drains to Tons river near  
82 Bajawala. The Tons river flows westward and confluence with river Yamuna. The length of  
83 the watershed extends 13 km North West.

84

85

86

**Map No. 4: Drainage**

**GEOLOGY :**The area of Dehradun is characterized by faults and fractures. The northern boundary of the district is formed by lesser Himalayan range and southern boundary Siwaliks. The Doon valley lies in the Middle and Upper Siwalik. This area is composed of fluvial sediments consisting of conglomerates and sandstone-mudstone complex. The conglomerates are predominantly composed of pebbles and boulders. The debris eroded from the steep slope hills in the northern part, deposits along a shallow longitudinal valley at the foot of the Himalayan range which are formed in the Siwaliks is called as 'Doon'. The continuous deposits in the valley caused the floor of the valley to raise.

Comment [u6]: grammar

Comment [u7]: rise?

98 **SOIL** :The nature and characteristics of soil play an important role in the growth and  
 99 development of crops, trees and other vegetation. The soil of the watershed shows large  
 100 variation due to variation in slope, topography and land use. Due to large variation in relief  
 101 and slope in the selected watershed, the soils subjected to erosion resulting in wide variation  
 102 with respect to texture , soil depth, organic matter, stoniness, color, drainage, moisture  
 103 content and cation exchange capacity. In the northern upper catchment area of watershed,  
 104 soil depth is less due increased erosion caused by steep slopes and are mostly covered by  
 105 scrub vegetation . In the upper catchment area, due to very steep slopes, the thickness of the  
 106 soil is very less and is considered as unproductive. As the slope decreases the soil depth  
 107 increase and land use change through forest in the lower hills and piedmonts to agriculture  
 108 in upper and lower piedmonts are seen.

109 **CLIMATE** :The watershed lies in the subtropical to semi-humid climatic region. The  
 110 average annual temperature ranges from 30.9 C in summer to 15.2 C in winter with an  
 111 average annual rainfall of 1700mm. The average annual rainfall during 2004 to 2013 is  
 112 2344.42 mm . Most of the rainfall is received during the south west monsoon. The months  
 113 of July and August receive the maximum rains. About 86.9 % of the rainfall is received  
 114 during monsoon season.

115 **Table No. 2 : Average Rainfall Distribution (2004-2013 )**

Sr.No.	Month	Average Rainfall (in mm )
1	January	34.86
2	February	103.99
3	March	35.87
4	April	22.82
5	May	56.11
6	June	310.87
7	July	688.62
8	August	362.01
9	September	362.01
10	October	39.57
11	November	4.63
12	December	8.86
	<b>Total</b>	<b>2344.42</b>

116

117 **DEMOGRAPHY** :As per the Census of India reports, the total population of Dehradun is  
118 5,78420 with male and female population of 303,411 and 275,009 respectively. The sex  
119 ratio of the city is 906 per 1000 male. The number of literates in Dehradun city is 463,791  
120 of which 251,832 are male and 211,959 are female. Average literacy rate of Dehradun city  
121 is 89.32 % whereas male literacy and female rate are 92.65 and 85.66% respectively.  
122 According to topographical map, about 20 numbers of the villages were identified. But out  
123 of 20, only 11 villages were reported by census of India. These 11 census villages are :  
124 Chhoba, Kedderwala, Chandpur (kala and Kurd), Rudarpur, Godrio, Surno, Barwa, Koti,  
125 Dubhal, Kotra ( Kalyanpur, santaup ), Kolwanpur, Birsani with the total population and of  
126 7268, 24 2 ( 224,183), 2136,2116, 1273,270, 651, (666,831 ) ,86 and 352 respectively.

Comment [u8]:

127  
128 **ECONOMY** :The economy of the study area is confined in the agricultural activities. Due  
129 to hilly terrain in the northern part, that tract is beyond any utility. Cultivation in the hill  
130 slope area is of two description, regular and intermittent. The hill, however, contain very  
131 little level ground and therefore, farmers follow terraced cultivation. Intermittent cultivation  
132 consists of small patches of hill sides cleared off shrubs and grass usually by fire.

### 133 **LITERATURE REVIEW**

134 In agriculture, soil erosion is major problem. The deterioration of soil by the physical  
135 movement of soil particles from a particular site is known as soil erosion. Wind, water, ice,  
136 animals, and the use of tools by man in agriculture are usually the main causes of soil  
137 erosion. The soil erosion is a natural process which usually does not cause any major  
138 problems, when its quantity is comparatively low. It becomes a problem when human  
139 activity causes it to occur faster than under normal conditions (Bakkar et al., 2005).

140 Worldwide, farmers are losing an estimated 24 billion tons of topsoil each year. In  
141 developing countries erosion rates per acre are twice as high as the standard, partly because  
142 population pressure forces land to be more intensively farmed. Although soil erosion is a  
143 physical process, it also affects productivity and growth. Reductions in yield of up to 50%

144 have been documented on severely eroded soils in Ontario. When soils are depleted and  
145 crops receive poor nourishment from the soil, the food provides poor nourishment to  
146 people. Losses of soil take place much faster than new soil can be created. It takes  
147 thousands of years to form just a few centimeters of soil. The difference between creation  
148 and loss represents an annual loss of 7.5 to 10 tons per acre worldwide. The main causes of  
149 soil erosion are still inappropriate agricultural practices, deforestation, overgrazing and  
150 construction activities (Yassoglou et al., 1998).

151 Hydrologic and other soil physical properties are particularly important factors  
152 affecting the potential for surface erosion. Coarse-textured soils are low in organic matter is  
153 most susceptible to surface erosion. Most undisturbed forest soils in the region have a high  
154 porosity which, coupled with the low intensity of most rainfall event, seldom result in  
155 overland flow. Prescribed fire and extensive human developmental activities can increase  
156 soil erosion on steep slopes. Accelerated erosion from human activity usually has a major  
157 effect on long-term forest and agricultural productivity and may pose severe threat in  
158 future. Therefore it is necessary to assess the risk due to soil erosion by assessing the  
159 quantity of soil eroded from the study area.

160 Keif and Yoshino (2010) has evaluated the economic effects of soil erosion risk on  
161 agricultural productivity using remote sensing. They have carried out the investigations in  
162 the Tunishi watershed. Their results showed that, the erosion risk increases in particular  
163 from mountainous areas to gentle areas and reported the fact that, the erosion risk occurs in  
164 areas with steep slope, poor vegetation, high soil erodibility and no erosion control.

165 The agriculture land is very sensitive for soil erosion as man carries out his most of the  
166 mechanization practices in it for the cultivation and growing of crop plants. Overall human  
167 activities carried out in agricultural land are acting as an important cause for increasing soil  
168 erosion from croplands. With this view many researchers are working in these areas. The  
169 impact of the land use on the risk of soil erosion from agricultural lands in Canada was  
170 reported by Shang Li et al. (2010) and they concluded that, Overall the risk of soil erosion

Comment [u9]: formed

171 on Canadian cropland was reduced steadily after 1980, because of adoption of conservation  
172 tillage, but till in some agricultural land the risk of soil erosion is there in some crops such  
173 as potato, sugerbeet, corn, soyabean etc.

174 Soil erosion is a physical phenomenon found in nature where surface soil is being  
175 drained from one place to other. The weathering agents, vegetation cover, soil type,  
176 topography of region, and geology of region are acting as an important factors influencing  
177 the soil erosion. Many researchers are assessing the soil erodibility risk in various places by  
178 employing Remote Sensing and GIS technologies. Tingting et al (2008) has assessed the  
179 soil erosion risk in Northern Thailand and reported that, the soil erosion risk is very high in  
180 the altitude between 100 and 400 m zone and it was found lower in forest area as compare  
181 to agriculture and plantation areas. Gitas et al (2009) has assessed the soil erosion risk in  
182 Chalkidiki from Greece by using LISS III data and modified USLE Raster model. They  
183 have modified the protocol for estimation of C and K factors. The USLE factors were  
184 determined as grid layer by processing data and prepared the soil erosion risk maps in three  
185 different seasons and determined its accuracy levels.

186 The result reveals that, the multi temporal NDVI gives better insights than a single data  
187 approach. In modern industrialized era the increase population is degrading the surrounding  
188 environmental parameters and which is posing various kinds of threats. The vegetation  
189 degradation is one of the threat resulted due to human development activities and which is  
190 posing the risk of soil erosion. The increased risk of soil erosion may cause adverse impact  
191 on agriculture as well on horticulture making it unsustainable. Therefore worldwide people  
192 are working on the soil erosion risk of particular areas with respect to deforestation and  
193 other factors in different watersheds. Lu Yuan and Hua Cui (2017) has evaluated soil  
194 erosion sensitivity in Guangxi area by using GIS based system and given affecting  
195 parameters on soil erosion.

## **MATERIALS AND METHOD-**

### **DATA BASE USED**

Comment [u11]: remove

To study the soil erosion risk at selected study area of Nun river watershed, the LISS III images of March 2016 was used. The DEM is used to delineate the watershed of Nun River and boundary was determined by employing the following methodology. By using the LISS III the soil erosion from the Nun river watershed was determined by using RUSLE model.

### **RAINFALL EROSIVITY (R) FACTOR:**

The R factor represents the erosive force of a specific rainfall event, The rainfall erosivity is an index of rainfall erosivity which is the potential ability of the rain to cause erosion. To produce R-factor map, the interpolated R- factors were converted into a raster format with 30 m resolution and extracted for the studied watershed.

**The equations for calculation of R-Factor is given below;  $R' = A + 0.329 * DEM$  layer**

$$R = 81.5 = 0.375 * R'$$

### **SOIL ERODIBILITY (K) FACTOR:**

The soil erodibility factor, K value is the rate of soil loss per rainfall erosion index unit as measure on standard plot and often determined using inherent soil properties. The K-factor is related to soil texture, organic matter content permeability, and other factors and it is basically derived from the soil type. K factor is the integrated effect of processes that regulate rainfall acceptance and the resistance of the soil to particle detachment and subsequent transport. Soil textural triangle was used to determine the soil textural class from the percentages of sand, silt and clay in soil.

### **SLOPE LENGTH (L):**

L-factor presents the effect of slope length on erosion. Slope length is the distance from the origin of overland flow along its flow path to the location of the either concentrated flow or deposition. In this case study LISS III data and ArcGIS software was used to

230 measure the slope length. Homogeneous field areas were delineated and slope length  
231 measured of many fields and length was generated.

#### 232 **SLOPE STEEPNESS (S):**

233 S factor represents effect of slope steepness on erosion as soil loss increases more  
234 rapidly with slope length. The relation of soil loss to gradient is influenced by density of  
235 vegetation cover and soil particle size. In this case study from SRTM 30 meters data DEM  
236 map was generated from which terrain slope map in degree and percentage was generated.

237

238

#### 239 **TOPOGRAPHIC FACTOR (LS):**

240 The LS factor reflects the effect of topography on erosion where slope length factor (L)  
241 represent the effect of slope length on erosion, and the slope steepness factor (S) reflects the  
242 influence of slope gradient on erosion. The LS factor is considered in the soil loss equation  
243 model due to the fact that both the length and the steepness of the slope substantially affect  
244 the rate of soil erosion by the water. The steeper and longer the slope, the higher is the rate  
245 of erosion by water because of the greater accumulation of runoff. The slope length and  
246 steepness values were drawn from the SRTM DEM (30 m resolution) using the Arc GIS  
247 Spatial analyst tool and the Arc Hydro tool. The resulting slope length (L) map indicated  
248 that the slope length varied from 0 to 102. The slope steepness (S) map showed that the  
249 slope gradient ranged from 07 to 2.46 in the lower and head stream of the watershed,  
250 respectively. Values for combined LS factor varied between 0 and 28.19.

#### 251 **LAND USE/ LAND COVER (C):**

252 The land use/ land cover (C) factor represents the ratio of soil loss from land covered  
253 by vegetation to the corresponding loss from continuous fallow. The C factor is the most  
254 important factor in RUSLE model due to its representation to reduce soil erosion.  
255 Supervised classification was performed to generate land use land cover map. The land use  
256 land cover map has been classified as forest, dense scrub, open scrub, agricultural land,

257 river and settlement. The land use land cover map of the study area was derived from LISS  
258 III image as the basis for determining the C factor values.

259 **CONSERVATION PRACTICE/SUPPORT PRACTICE FACTOR (P):**

260 The P factor is the ratio of soil loss with a specific support practice to the  
261 corresponding loss with up slope and down slope tillage. The lower P value, the more  
262 effective the conservation practice is deemed to be at reducing soil erosion. The  
263 conservation practices (P) factor are also known as erosion control practice factor is the  
264 ratio of soil loss with a specific conservation practice like contouring, strip-cropping, or  
265 terracing measures to the corresponding loss with up and down slope cultivation. Thus, the  
266 P factor for RUSLE can be mapped through by collecting data from frequent field  
267 observations. The P factor ranges from 0 to 1, where the highest value is allocated to areas  
268 with no protection practices.

269 **Methodology Used:** The revised Universal Soil Loss Equation "RUSLE" model aims at  
270 predicting soil loss from lands due to soil erosion by water. This is universally accepted. It  
271 is based on 5 factors related to rainfall (R), soil characteristics (K), topography (LS), land  
272 use (C) and cover management (P).

Comment [u12]: remove

273 It can be written as;

$$274 A=R*K*LS*C*P$$

275 Where,

276 A=The annual land loss (ton/ha/year)

277 R = Rainfall erosivity factor ( $\text{MJ mm ha}^{-1} \text{IT}^{-1} \text{yr}^{-1}$ )

278 K= Erodibility factor (ton ha hr/ha.MJmm)

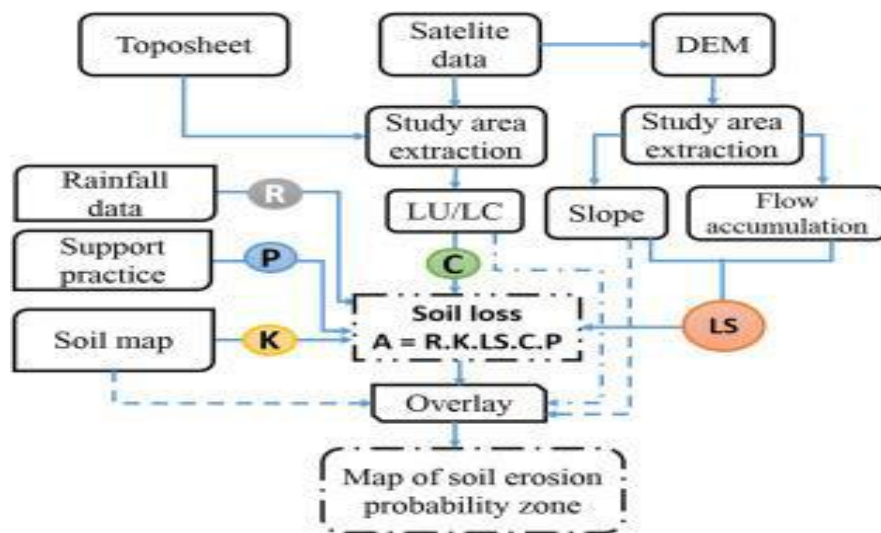

279 LS= Slope length and slope indication factor

280 C= Vegetation cover Management factor

281 P = Supporting practices factor while 'C, P and LS are dimensionless.

282 In this study, these 5 factors are represented on a raster with a cell resolution of 30\* 30m  
283 and geo-referenced to the Universal Traverse Mercator WGS 84 (Zone 44 N). These are

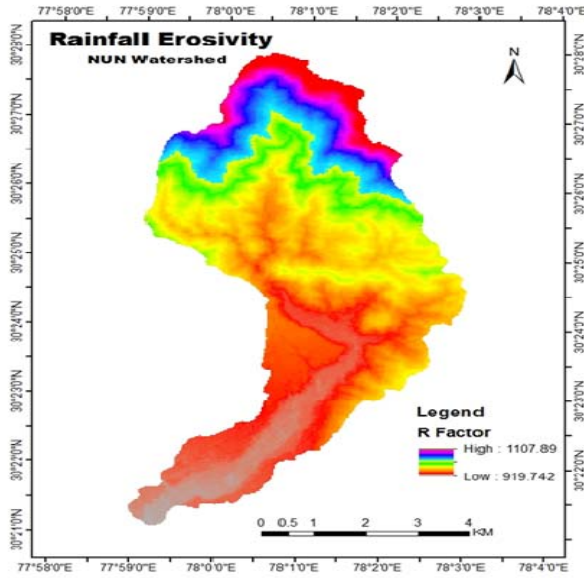

284 computed by using suitable datasets and appropriate software such as ERDAS imagine and  
285 ArcGIS 10.3

### RESULTS AND DISCUSSION:

**Rainfall Erosivity (R) Factor** – The average rainfall of the twenty five years is 2051.4 mm and the average annual R factor value varies from 919.74 to 1107.89 MJ ha/mm/hr/yr. The mean value is 1013.82MJ ha/mm/hr/yr. The rainfall erosivity was found to be more in the northern part of watershed as compared to southern part which is indicative of the decrease in the rainfall from north to south and a reflection of spatial variation in erosivity of the area.

Map No. 5: Rainfall Erosivity

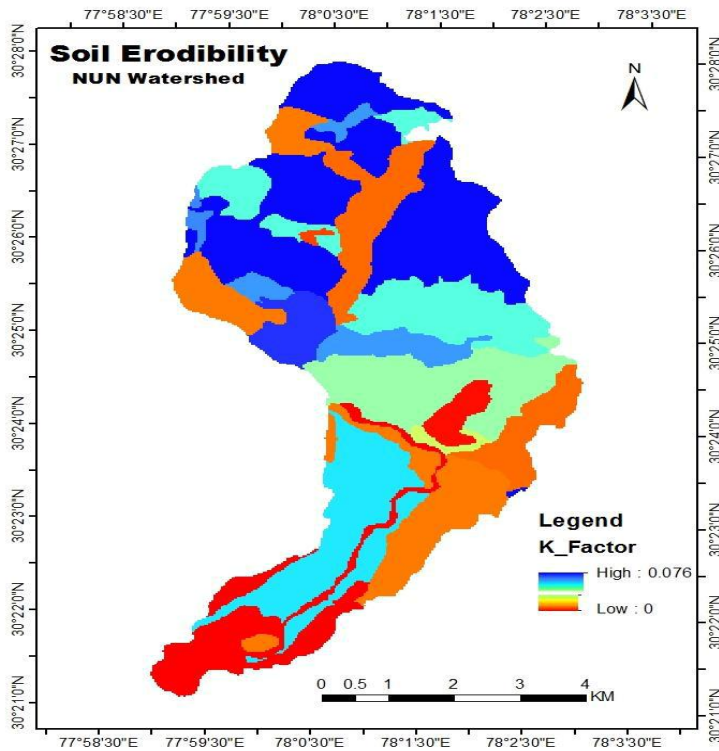

**Soil Erodibility (K) factor** – The K value in the study area ranged from 0 to 0.07 th MJ<sup>-1</sup> mm<sup>-1</sup> and the mean value is 0.038 th MJ<sup>-1</sup> mm<sup>-1</sup>. The K map show spatial distribution of soil erodibility. It can be seen for the K map that the soil erodibility was found to be higher in the northern part mostly dominated by open scrub.

473 **Conservation Practices / Support practice factor (P factor) :** The P factor value  
474 varies from 0 to 1 and the mean value is 0.78. From the P map may be inferred that  
475 owing to the hilly topography, majority of the areas in the watershed is engaged in  
476 some conservation practice.

*Map No. 10: P Factor*

**Soil Risk Assessment:** After completing data input procedure and preparation of R, K, C, P and LS maps are data layers, they were multiplied in GIS environment to draw up the erosion risk map showing the spatial distribution of soil loss in study area. The annual soil loss was calculated after obtaining the product of R, K, LS, C, F as factors for soil erosion. The annual soil loss for the Nun watershed varies from 0 to 354 ton/ha/yr. The average annual soil loss is 24.82 ton/ha/yr. Majority of the watershed falls under low erosion risk class excepting few patches in the northern part which is very highly susceptible soil erosion owing to topography and low vegetation. Prevalence of forest cover may account for less susceptibility to soil erosion almost in the entire of Nun watershed.

658

659 **CONCLUSION:**

660

661 The study area under taken is a part of Dehradun District, Uttarakhand with an  
 662 aim to assess the soil erosion risk and model by using RUSLE in the Nun  
 663 watershed. Remote Sensing and GIS techniques along with field generated data on  
 664 soil characteristics was used for assessing the risk of soil erosion. From Cartosat 3  
 665 30 m DEM, delineation of the study area (Nun watershed) was identified. In this  
 666 identified study area LISS III image was used to estimate the soil erodibility.

667

668 **The finding of the study shows.**

669

670 • The annual average soil loss of the Doon watershed was found to be 24.82

671 ton/ha/yr.

672 • It is clearly evident that the major cause of soil erosion is slope, steepness, heavy  
 673 rainfall and nature of vegetation cover are influencing the soil erodibility.

674 • Highest soil loss was observed in open scrub area followed by agriculture, dense

675 scrub and minimum in forest dominated areas.

676

677 Using RUSLE MODEL, conservation measures can be suggested depending on the  
678 amount of soil eroded from the particular area.
