#### 1 Plant Regeneration via Somatic Embryogenesis in *Solanum nigrum* L.(black nightshade)

- 2 (Solanaceae)
- 3

# 4 ABSTRACT

5 Aim: To study the effect of various plant growth regulators (PGRs) for induction of somatic

- 6 embryogenesis and plantlet formation from cotyledon and leaflet explants in *S.nigrum* (night
- 7 shade) an important medicinal plant used in treatment of digestive problems and skin infections.
- 8

9 Place and Duration of study: Department of Biotechnology, Kakatiya university, Warangal.

- 10 Telangana, India, 3years.
- 11

12 **Methodology:** Cotyledon  $(0.8 \text{ cm}^2)$  and leaflet explants  $(0.8-1.0 \text{ cm}^2)$  from 3 week and 4 week

13 old were cultured on MS medium supplemented with 30 g/L sucrose along with different

14 concentrations of 0.5 mg/L BAP+NAA (0.5 - 6.0 mg/L).

15

16 **Results:** Maximum percentage of somatic embryogenesis was observed in cotyledon(89%) and

17 leaf (98%) explants on MS medium augmented with 0.5mg/L BAP in combination with 2.0

18 mg/L NAA whereas the highest number of somatic embryos per explant ( $86 \pm 0.19$ ) was formed 19 in leaflet explant.

20

21 **Conclusion:** Somatic embryogenesis was induced from both cotyledon and leaf explants. Since

22 it is threatened and medicinally important species *S.nigrum*, the present protocol can be used for

23 its conservation and genetic transformation experiments.

24

25 Keywords: *Solanum nigrum*; somatic embryogenesis; acclimatization; plantlet establishment.

# 31 **1. INTRODUCTION**

Somatic embryogenesis provides an efficient method for plant micropropagation and conservation of the species [1,2]. The plants regenerated via somatic embryogenesis are of single cell origin with *true-to-type* and are produced in large numbers within a short period [3,4]. Somatic embryogenesis is a preferred method for rapid *in vitro* multiplication of plants, production of artificial / synthetic seeds and also for *Agrobacterium tumefaciens* mediated genetic transformation and regeneration of transgenic plants [5].

Following the initial reports of Reinert [6] and Steward et al. [7], the phenomenon of somatic embryogenesis was reported in a number of medicinal plants: *Solanum melongena*  40 [8,9,10&11], Solanum quitoense [12] Solanum lycopersicum [13], Tribulus terrestris [14],
41 Psoralea corylifolia [15], S. surattense [5] and Senna alata [16].

The species Solanum nigrum (Solanaceae) is an important ingredient in traditional Indian 42 medicines. Infusions are used in dysentery, stomach complaints, and fever. The juice of the plant 43 used other skin diseases. The is on ulcers and fruits are used 44 as a tonic, laxative, appetite stimulant, and for treating asthma and "excessive thirst". Traditionally 45 the plant was used to treat tuberculosis. It is known as peddakasha pandla koora in 46 the Telangana region. The leaves are used to treat mouth ulcers that happen during winter 47 periods. It is known as *manathakkali keerai* in Tamil Nadu and *kaage soppu* in Karnataka, and 48 49 apart from its use as a home remedy for mouth ulcers, is used in cooking like spinach. In North India, the boiled extracts of leaves and berries are also used to alleviate liver-related ailments, 50 51 including jaundice. In Assam, the juice from its roots is used against asthma and whooping cough. S. nigrum is a widely used plant in oriental medicine where it is considered to be 52 antitumorigenic, antioxidant, anti-inflammatory, hepatoprotective, diuretic, 53 and antipyretic. S.nigrum is known to contain solasodine (a steroidal glycoalkaloid that can be used to make 16-54 55 DPA progenitor); a possible commercial source could be via cultivating the hairy roots of this plant [17,18]. 56

57 Inview of its medicinal importance the plant has become threatened/endangered. Hence we have

developed the protocol for plant regeneration via somatic embryogenesis for conservation of the
 medicinally important species *S. nigrum*.

60

#### 61 2. MATERIALS AND METHODS

#### 62 **2.1 Plant Material:**

For somatic embryo induction and plantlet formation the seeds of *S.nigrum* were soaked in sterile distilled water for 24 hrs. These were sterilized with 70% (v/v) alcohol for 2-3 minutes(treatment uniform) followed by 1% (w/v) aqueous solution of sodium hypochlorite for 3-5 minutes (treatment uniform). Later, the sterilized seeds were washed thoroughly with sterile distilled water and were germinated aseptically on MS [19] basal medium.

68

## 69 **2.2 Culture Media and Culture Conditions:**

- The explants viz., cotyledon  $(0.8 \text{ cm}^2)$  and leaf  $(0.8-1.0 \text{ cm}^2)$  from 3 weeks and 4 weeks old axenic seedlings respectively were transferred on to MS medium containing 30 g/L sucrose along with different concentrations of NAA (0.5 - 6.0 mg/L) + 0.5 mg/L BAP.
- For further proliferation the explants with somatic embryos were cultured on MS medium
   augmented with 0.5 mg/L BAP + 2.0 mg/L NAA.

For germination and plantlet formation, the bipolar (torpedo-shaped) stage embryos were transferred onto  $\frac{1}{2}$  strength MSO, MSO and MS medium fortified with different concentrations of BAP (1.0 – 3.0 mg/L) + 0.5 mg/L IAA. The pH of the medium was adjusted to 5.8 prior to addition of 0.8% (w/v) Difco-bacto agar and autoclated at 121°C for 15-20 minutes. All the cultures were incubated under 16/8 h light / dark photoperiod at 25±2°C.

80

#### 81 **2.3 Data Analysis:**

Data were recorded after 4 weeks of culture. Each experiment was repeated at least twice and 20 replicates were maintained for each experiment.

#### 84 **3. RESULTS:**

The induction of direct somatic embryos and plantlet formation from cotyledon and leaf explants was studied on MS medium augmented with 0.5 mg/L BAP in combination with 0.5-6.0 mg/L

NAA in *S. nigrum*. The results are presented in Tables 1-3 and shown in Fig.1.

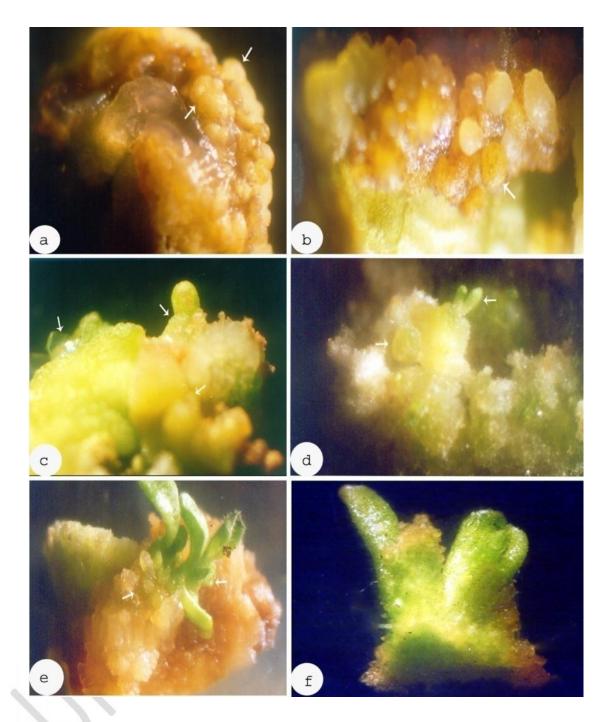

88

### 89 **3.1 Somatic embryogenesis from cotyledon explants:**

The cotyledon explants were cultured on MS medium fortified with different 90 concentrations of NAA (0.5 - 6.0 mg/L) + 0.5 mg/L BAP. Cotyledon explants were swollen 91 after 4 days of culture and globular somatic embryos were induced from the explant after 10 92 93 days of culture (Fig.1 a, b). Somatic embryogenesis was induced from the cotyledon explants 94 cultured on all the concentrations of NAA + 0.5 mg/L BAP except at 6.0 mg/L NAA in which callus was induced. High percentage (89) of somatic embryogenesis with maximum frequency 95 number (65 $\pm$ 0.23) of somatic embryos formation was observed at 2.0 mg/L NAA + 0.5 mg/L 96 BAP. As the concentration of NAA in combination with BAP increased, the percentage of 97 somatic embryo induction and as well as somatic embryo number per explant were enhanced 98 upto 2.0 mg/L NAA (Table 1). But at high concentration of NAA + 0.5 mg/L BAP, the 99 percentage of somatic embryogenesis was reduced. 100

101 Globular embryos were converted into bipolar embryos on all the concentrations of NAA 102 used except at 4.0 & 6.0 mg/L NAA + 0.5 mg/L BAP. The embryo conversion was found to be 103 dependent on the level of NAA. High percentage of bipolar / torpedo-shaped embryos formation 104 was recorded at 2.0 mg/L NAA(Fig.1c-e). Less percentage of conversion and absence of 105 somatic embryo conversion was observed at 3.0 & 4.0 g/L NAA respectively.

For further proliferation of somatic embryos, the explants with embryos were cultured on MS medium supplemented with 2.0 mg/L NAA + 0.5 mg/L BAP. Further maturation of somatic embryoids was absent even after  $2^{nd}$  subculture on the fresh medium containing the same PGRs.

109 110

- Fig.1 a-m: Induction of somatic embryogenesis from cotyledon(a-h) and leaf(i-j) explants
  of *S. nigrum*
- a) Globular embryoids on MS + 0.5 mg/L BAP + 1.0 mg/L NAA; b) Many Globular embryoids
- on MS + 0.5 mg/L BAP+2.0 mg/L NAA; c) Globular and torpedo-shaped embryos on MS + 0.5
- mg/L BAP + 2.0mg/L NAA after 1st subculture; d) Globular and heart-shaped embryoids after
- 116 1st subculture on MS  $\pm 0.5 \text{ mg/L BAP} \pm 2.0 \text{ mg/L NAA}$ ; e) Various stages of embryoids (Note
- the cotyledonary stage embryoid) after 6 weeks of culture; f) Cotyledonary stage and torpedo-
- shaped embryoids on MS+0.5mg/L IAA+1.5mg/L BAP after 6 weeks of culture.

#### **3.2 Somatic embryogenesis from leaf explants:** 124

Leaf explants of S.nigrum were cultured on MS medium augmented with different 125 concentrations of NAA in combination with 0.5 mg/L BAP (Table 2). Somatic embryogenesis 126 127 was initiated from the explant in all the concentrations of NAA except at high concentration (6.0 mg/L NAA). As in the cotyledon explant, the somatic embryogenesis was inhibited at 6.0 mg/L 128 NAA + 0.5 mg/L BAP and callus was induced. Somatic embryoids were formed after 10 days of 129 culture. High percentage of somatic embryogenesis was observed at 2.0 mg/L NAA followed by 130 1.5 mg/L NAA + 0.5 mg/L BAP. Whereas maximum frequency number of somatic embryos per 131 explant was observed at 2.5 mg/L NAA(Fig.1i). Less number of somatic embryo induction was 132 recorded at 4.0 mg/L NAA. As the concentration of NAA increased, there is an increase in the 133 average number of somatic embryos development per explant upto 2.5 mg/L NAA. 134

The conversion of somatic embryos from globular to torpedo-shaped was found in all the 135 concentrations of NAA tested with an exception of 4.0 mg/L NAA. Maximum percentage of 136 bipolar embryos was recorded at 2.0 mg/L NAA + 0.5 mg/L BAP. 137

For further proliferation and maturation of somatic embryos, the leaf explant consisting 138 of somatic embryos in different stages (globular to bipolar) was transferred onto fresh medium 139 containing 2.0 mg/L NAA + 0.5 mg/L BAP. Bipolar somatic embryos did not mature further 140 even after 2<sup>nd</sup> subculture on the same fresh medium. But the somatic embryos number per 141 explant was enhanced. 142

Individual embryos developed into distinct bipolar structures and passed through each of
the typical developmental stages (globular, heart, torpedo / bipolar) after 4-6 weeks of culture.
The development of somatic embryos was asynchronous. As a result, various stages of embryo
development could be observed in the same cluster of embryos originated from the explants
(Fig.1e).

152 153

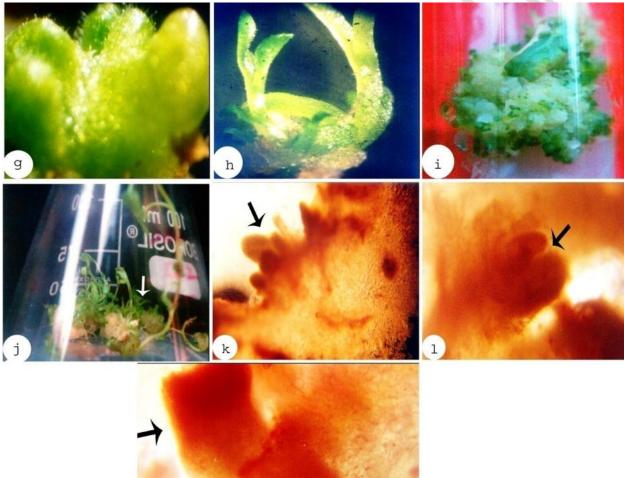

#### 154 **3.3 Somatic embryo germination & plantlet formation:**

For germination of somatic embryos, globular, heart and torpedo-shaped embryos (a 155 mixture) developed from cotyledon and leaf explants were transferred on to 1/2 strength MS 156 medium, MS medium without growth regulators and MS medium supplemented with different 157 concentrations of BAP in combination with 0.5 mg/L IAA (Table 3). Somatic embryos did not 158 germinate on <sup>1</sup>/<sub>2</sub> strength MS medium and also on MS medium without PGRs.. The highest 159 (73.8%) frequency of embryo germination was noticed on medium containing 0.5 mg/L IAA + 160 1.5 mg/L BAP. Whereas embryo germination frequency was reduced at high concentration of 161 BAP. 162

Histological sections of embryo forming explants clearly revealed a globular-shaped embryo, a heart-shaped embryo with a notch and two cotyledons and torpedo-shaped embryo with shoot and root poles (Fig.1 k-m) upon transfer to a medium containing 0.5 mg/L IAA + 1.5 mg/L BAP, the embryos turned green with folded cotyledons, which subsequently developed into whole plantlets (Fig. 1j.)

Plantlets regenerated via somatic embryogenesis were transferred to polycups containing mixture of soil and sand in ratio of 3 : 1 with 75% survival rate. A total of 30 regenerated plants were transferred to earthenware pots from the polycups and maintained in the research field under shady conditions. These *invitro* regenerated plants via somatic embryogenesis were found

similar to donar plant.

# 187 **4. DISCUSSION:**

Somatic embryogenesis was induced directly from the cotyledon and leaf explants 188 in S.nigrum on MS medium fortified with different concentrations of NAA (1.0 - 6.0)189 mg/L) in combination with 0.5 mg/L BAP except at 6.0 mg/L NAA. The present 190 investigations showed that auxins such as NAA along with cytokinins BAP are required 191 for inducing the somatic embryogenesis. For somatic embryogenesis the nature of PGRs 192 and their concentration and combinations used in the culture medium play a vital role. 193 The type of auxin or auxin in combination with cytokinin used in the induction medium 194 can greatly influence somatic embryo frequency. The requirement of cytokinin in 195 addition to auxin was observed in medicinal plants like *Terminalia arjuna* [20], and 196 *Psoralea corylifolia* [15], as it was observed in the present studies. Somatic 197 embryogenesis was induced on medium containing NAA alone in Solanum melongena 198 [21, 22, 23]. Recently, Rama swamy et al [5] have also reported the essentiality of both 199 auxin-cytokinin combination for inducing somatic embryogenesis in an endangered 200 medicinal plant S.surattense a medicinal plant. 201

In the present investigations, leaf explants showed maximum frequency number of somatic embryos production and also conversion into bipolar embryos at 2.0 mg/L NAA + 5.0 mg/L BAP compared to cotyledon explants. Similarly it was also observed in *S.surattense* [5].

BAP induced the direct somatic embryogenesis and also the number of embryos further increased by enriching the medium with NAA in *Hippeastrum hybridum* [24]. Similar findings were also made by Cavillini and Natali [25] in *Brimeura amethystina*. Sahrawat and Chand[15] have also observed the high frequency somatic embryogenesis

in hypocotyl explants on MS medium supplemented with NAA (1.4  $\mu$ M) + BAP (2.2 210 µM) in Psoralea corvlifolia, whereas somatic embryogenesis was reported on medium 211 containing NAA alone in *Solanum melongena* [25]. 212

Somatic embryo maturation is a critical step in somatic embryogenesis which 213 leads to the complete plantlet formation. In the present investigation both auxin and 214 cytokinin combination favoured the maturation and germination of somatic embryos. 215

This is probably because of conversion of some of the heart-shaped embryos to 216 torpedo or cotyledonary stage embryos and their subsequent germination in the presence 217 of IAA+BAP. Thus, a combination of IAA+BAP combination seems to be necessary for 218 maturation and germination of bipolar somatic embryos in *S.nigrum*. Prakash et al [26] 219 have reported that TDZ (1.0 mg/L) in combination with GA<sub>3</sub> (1.0 mg/L) was found to be 220 comparatively more effective than BA for somatic embryo maturation in Pimpinella 221 tirupatiensis an endangered medicinal plant. The requirement of auxin-cytokinin 222 combination was also reported in *S. surattense* and *S. lycopersicum* for germination of 223 torpedo-shaped embryos [5, 13] as it was noted in the present investigations. 224

According to Zimmerman [27] new gene products are needed for the progression 225 from the globular to the heart-stage and these new products are synthesized only when an 226 exogenous auxin is removed. But, according to our observations in S.nigrum for 227 induction of somatic embryos, auxins and cytokinin combination is required. At higher 228 concentration of auxin probably the population of embryogenic cells drops due to their 229 disruption and elongation and the embryogenic potential of the culture is lost [28]. 230 Similarly, in the present investigation embryogenesis was inhibited at 6.0 mg/L 231 concentration of NAA + 0.5 mg/L BAP. 232

Whereas Garin et al [29] reported that the entire process of induction and 233 maturation of the embryos was completed on the same MS medium containing auxins 234 and cytokinins (2,4-D + TDZ) in Capsicum annuum as it was observed the requirement 235 of both the hormones in the present investigations. Similarly, somatic embryos 236 maturation on MS medium containing the combination of auxins (NAA) and cytokinins 237 (BAP) was observed in *Prunus avium* [30]. 238

Thus, Somatic embryogenesis always appeared to be dependent on the type of 239 auxin / cytokinin / auxin + cytokinin and their concentrations in the medium. The type of 240 growth regulator and its concentration also varies from genotype to genotype. High 241 concentration of auxin in combination with less concentration of cytokinin induced the 242 somatic embryogenesis and maturation of somatic embryos in S.nigrum. However, for 243 germination of somatic embryos, low level of auxins and high concentration of cytokinin 244 combination is required. 245

Regeneration via somatic embryogenesis is better for obtaining genetically 246 uniform plants than through organogenesis. It is evident from the present studies that the 247 somatic embryogenesis in this species will be useful in the conservation and 248 improvement of this threatened medicinally important species S.nigrum. Somatic 249 embryogenesis is also preferred because it allows production of plants without 250 somaclonal variation and also used for genetic transformation [31]. These somatic 251

embryoids induced in *S.nigrum* can also be used for development of synseed technologyfor germplasm storage, conservation and also for exchange.

Thus, for induction of *in vitro* somatic embryogenesis the type of primary explant, genotype and growth regulators concentration and combinations play an important role. The protocol developed in the present investigation can be used for mass–scale propagation of *true-to-type* of *S.nigrum*.

258

**5.CONCLUSION:** In conclusion, this is the first report of a successful procedure to regenerate **Solanum nigrum** (Solanaceae) via somatic embryogenesis. The cotyledon explants were proved to be efficient for in vitro somatic embryogenesis compared to leaflet explants in *S.nigrum*. MS medium supplemented with higher amounts of auxins in combination with lower concentrations of cytokinins favor the induction and proliferation of somatic embryogenesis. Thus, the present reproducible regeneration protocol can be used for mass multiplication, genetic transformation, artificial seed production and cryopreservation of the important medicinal plant *S.nigrum*.
