ABSTRACT

To determine mother's perception and management of fever in their children. It was a descriptive cross-sectional study, carried out at the children outpatient clinic of the department of Paediatrics, University of Port Harcourt Teaching Hospital, over a oneyear period, January to December, 2012. Every mother who presented with her child to the children outpatient clinic was recruited and interviewed using a structured questionnaire after obtaining written informed consent, as they presented their children to the children outpatient clinic of the University of Port Harcourt Teaching Hospital until we recruited 324mothers, whose children aged between 0-16 years into the study. A little over half of these mothers had completed secondary education. The thermometer was used by 209(64.50%) mothers and the preferred route was by mouth 135(41.67%). 175(54.01%)mothers reported temperature < 35 °C as fever. 49.07% of the mothers were worried about the consequences of the fever. 43(13.3%) would give paracetamol. 24(7.4%) would tepid sponge. 15(4.6%) would give a cold bath. 6(1.9%) expose the child to air with reduced clothing. 4(1.2%), wrap the child with warm and thick cloth. 2(0.6%) gave antibiotics. 11 (3.4%) gave antimalaria. 6(1.9%) gave teething drugs. 1 (0.3%) gave nothing. Most mothers got their information on knowledge of fever management from doctors and nurses-164(50.62%). Paracetamol was the most commonly used drug by mothers for the treatment of fever at home-217 (67%). 87(26.852%) would take the child to hospital if fever persisted. This study found a significant association between using physical methods such as giving cold bath to reduce fever, and tepid sponging to reduce fever with no formal education P < 0.0001 and P< 0.0165 respectively. Data was analyzed using Epi-info version 7. Mothers awareness of fever in Port Harcourt is low and Paracetamol is commonly given to children with fever.

KEY WORDS: Fever, mothers, Perception, management

1. Introduction

Fever is a very common complaint accounting for 70% of the presenting complaints to the children outpatient clinic and general medicine outpatient department. [1] A lot of wrong perceptions about fever in children has led to high parental anxiety that is known globally [2] in 1980, thirty-nine years ago a man called Barton Schmitt had described parental concerns and anxiety about fever and called them Fever Phobia [3] This fever phobia makes parents and caregivers manage fever over aggressively and sometimes used wrong dosage of antipyretics to treat their children [4] Parents dearth of knowledge about the cause of fever and its effect on the health of their children, results in excess of fear and anxiety [5] There are several reports on parents perception of fever and its managem<mark>ent[1,6, 7, 8</mark>] which have brought out the fact that parents knowledge of fever management is not adequate, as a result they use wrong dosage of antipyretics according to Waish et al [4]. Very few parents (3.5%) knew the correct temperature definition for fever and 44.4% determined fever by touching the child's forehead [1] as reported by Rkain and co-workers. According to Luay Al-Noun and Khalid Basheer [9], 12% of mothers actually added more clothes or even covered with blankets in an effort to induce sweating on the assumption that

sweating will end fever. 67% of mothers did not know the correct body temperature according to Luay Al-Noun and Khalid Basheer working in Bagdad. There were evidently wrong methods of measuring fever and reducing it [10,11]. These differences in the knowledge and management of fever in different countries may have resulted from differences in geography, demography and education between these countries Educational programs have been reported to positively influence parents management of fever [12]. There is a dearth of knowledge regarding mothers' perception of fever in children. The aim of this study was to elucidate the perception of mothers and to compare our findings with what is happening in other regions.

2. Materials and Methods

2.1 Study area

Children outpatient clinic of the Department of Paediatrics, University of Port Harcourt Teaching Hospital. It is a Tertiary hospital located in Port Harcourt, Southern Nigeria. The Paediatrics department provides both inpatient and outpatient care.

2.2 Study population

The study population consisted of mothers who presented their children to the children outpatient clinic of the department of Paediatrics at University of Port Harcourt Teaching Hospital. The children aged between 0-16 years and their mothers consented for the study.

2.3 Selection and inclusion criteria

2.3.1 Inclusion criteria

Every Parent/ caregiver who brought their child or ward to the children outpatient clinic during the study period and consented for the study.

2.3.2 Exclusion criteria

Every Parent/ caregiver who brought their child or ward to the children outpatient clinic during the study period and did not give consent for the study

2.4 Sampling method

A non-probability sampling technique (Opportunistic sampling method) was used. All the mothers in the children outpatient clinic who were approached agreed to be part of the study. Every next mother who brought their child to the clinic was recruited until we had 324 subjects.

The study was conducted over a one-year period January to December 2012. A structured questionnaire was used. The questionnaire was designed to retrieve information on mothers' biodata, their knowledge, perception, fears and management of their children/wards fever at home.

2.5 Data management and analysis

Data was collected using a structured questionnaire, and entered into Microsoft excel spread sheet and analysis was done using Epi-info version 7

3. Results and Discussion

Three hundred and twenty-four mothers who brought their children to the children outpatient clinic of the department of Paediatrics at the University of Port Harcourt teaching hospital were recruited and interviewed. Over half of the study population, 183 (56.48%) completed secondary education, close to half of the mothers 161 (49.69%) were aged between 30 years to 39 years. Eighty- three (25.62%) of the mothers were business mothers, 39 (12.04%) were civil servants. 56(17.28%) were housewives. 33 (10.19%)

were students. 76 (23.46%) were unemployed. Most of the mothers, one hundred and sixty-four (50.62%) got information on fever management from doctors and nurses followed by relatives and friends 113(34.87%). 159(49.07%) were worried about the consequences of fever. 175(54.01%) mothers defined fever as temperature < 35 °C. Oral route was the most preferred route of monitoring fever by mothers 135 (41.67%). It is worrisome that 4mothers (1.2%) would wrap the child with warm and thick clothes in the presence of fever. 43 (13.3%) gave paracetamol (acetaminophen) to relieve fever at home, while 217 (67.0%) would give paracetamol as the preferred analgesic for relieving fever. Eighty -seven mothers (26.852%) would take their child to hospital if fever persisted. There was a significant association between using physical methods such as giving cold bath to reduce fever, and tepid sponging to reduce fever with no formal education P < 0.0001 and P< 0.0165 respectively.

Discussion: This work was on mothers' perception of fever, its monitoring and management in Port Harcourt, Nigeria. Similar to the work of Rkain and coworkers in Morocco [1]. About half of the mothers in this study completed secondary education, there ages ranged from 20years to over 50years and most of them were business women. Roughly half of them were unable to correctly define fever, they reported temperature < 35 °C as fever which is comparable to the findings of Rkain et al in Morocco where more than half of the parents did not know the correct temperature for fever [1]. Oral route 135 (41.67%) and rectal route 13 (4.01%) were the preferred routes by mothers in this study for recording their children's fever, this is in keeping with the findings of Athamneh et al [6] working in Jordan where oral and rectal routes were the preferred routes of monitoring children's fever by mothers in Jordan. Although this is in contrast to the NICE guideline which recommends the axilla as the recommended route [13]. Thota et al [14] in India reported that over 90% of parents in their study used the armpit (axilla) in recording their children's fever which is in keeping with the NICE guideline [13]. Parents should therefore be encouraged to use the axilla as a preferred route for monitoring their children's temperature. Physical methods of temperature reduction offer little benefit and cause crying and shivering in some children. It has been reported that they should not be encouraged [13,15]. These physical methods to reduce fever are therefore not recommended except in cases of hyperthermia [13]. 43.75% of mothers in this study who responded to the method they use in reducing their children's fever said they used physical methods. Rkain et al [1] reported that towel soaked in water was used by parents to reduce children's fever in Morocco while Zyoud and coworkers [16] reported that tepid sponging was used in Palestine and Chang et al [17] working in Taiwan reported use of herbal medicines among other methods. Parents should therefore be educated not to use physical methods in reducing their children's fever. The NICE guideline [13] recommends the use of antipyretics Paracetamol or Ibuprofen for reducing children's fever. Paracetamol is the most widely used antipyretics and its dose is10- 15mg/kg body weight/dose every 4-6hours. [12] In this study, about 13.3% of the mothers administered paracetamol in attempt to reduce their children's fever. Majority of Moroccan parents used paracetamol to reduce their children's fever. [1] 12.87% of the mothers used other not recommended drugs such as antibiotics 2%, antimalaria 14%, teething drugs 2%, herbal drugs 1% etc. Use of herbal medicines was also reported in Taiwan by Chang et al [17] and is comparable to the finding in this study while Athamneh et al reported 77% antibiotic use in reducing fever [6]. It is worrisome that mothers are still using herbal medicines to reduce their children's fever as they may be harmful. 49.07% of the mothers in this study worried most about the complications of the fever, although these complications were not specified, it's in keeping with other studies where parents worried about the harmful effects of fever on their children [1, 18]. Athamneh et al [6] found the most harmful effect reported by parents to be brain damage [6]. 34.87% of the mothers in this study got information on knowledge of fever management from relatives and friends, this is a common practice in south urban Indian population as reported by Thota et al who reported an association between the advising source of antibiotics (other than doctors)and inappropriate fever management practices.[14] This study found a significant association between using physical methods such as giving cold bath to reduce fever, and tepid sponging to reduce fever with no formal education P < 0.0001 and P< 0.0165 respectively. Studies have shown that educational level, socioeconomic status and cultural backgrounds are the major factors that determine knowledge and judgement of childhood fever [3,4]. It is not surprising therefore in this study to find mothers with no formal education being the most in using physical methods to reduce fever.

Conclusions.

This study found a poor knowledge of fever management among mothers who bring their children to the children outpatient clinic of university of Port Harcourt Teaching hospital. Mothers are still using physical methods to reduce their children's fever contrary to the NICE guideline. It is encouraging that Paracetamol is the most commonly used antipyretics by mothers to reduce their children's fever. Mothers with no formal education are more likely to use physical methods to reduce their children's fever than the educated mothers. I would recommend that Paediatric association of Nigeria should come up with a guideline on Childhood fever management practice. This will help our mothers.

LIMITATIONS

This was a hospital-based study and as such its findings would not be a good representation of mother's knowledge and practice of childhood fever management practices by mothers in the community. It will be good to replicate this study in the community.
