

**Estimation and Assessment of Soil Erosion Risk of Nun Watershed  
Using *Remote Sensing and GIS*.**

This study aims to investigate the soil erosion from selected watershed from Dehradun area having hilly terrain and human's development activities. The remote sensing based model was decided to perform the estimations and assessment of soil eroded from watershed. The Nun river watershed was selected for study. From the estimated quantity of soil eroded we can predict the risk due degraded soil in terms of decreasing crop productivity. The present study assists to decide the optimum land use for specific purpose at the Nun watershed in Deharadun, Uttarakhand. The major objective of the study is to assess the soil erosion risk in the study area.

**Keywords :- Soil erosion, Assessment, RS, GIS, Crop Productivity**

**INTRODUCTION-**

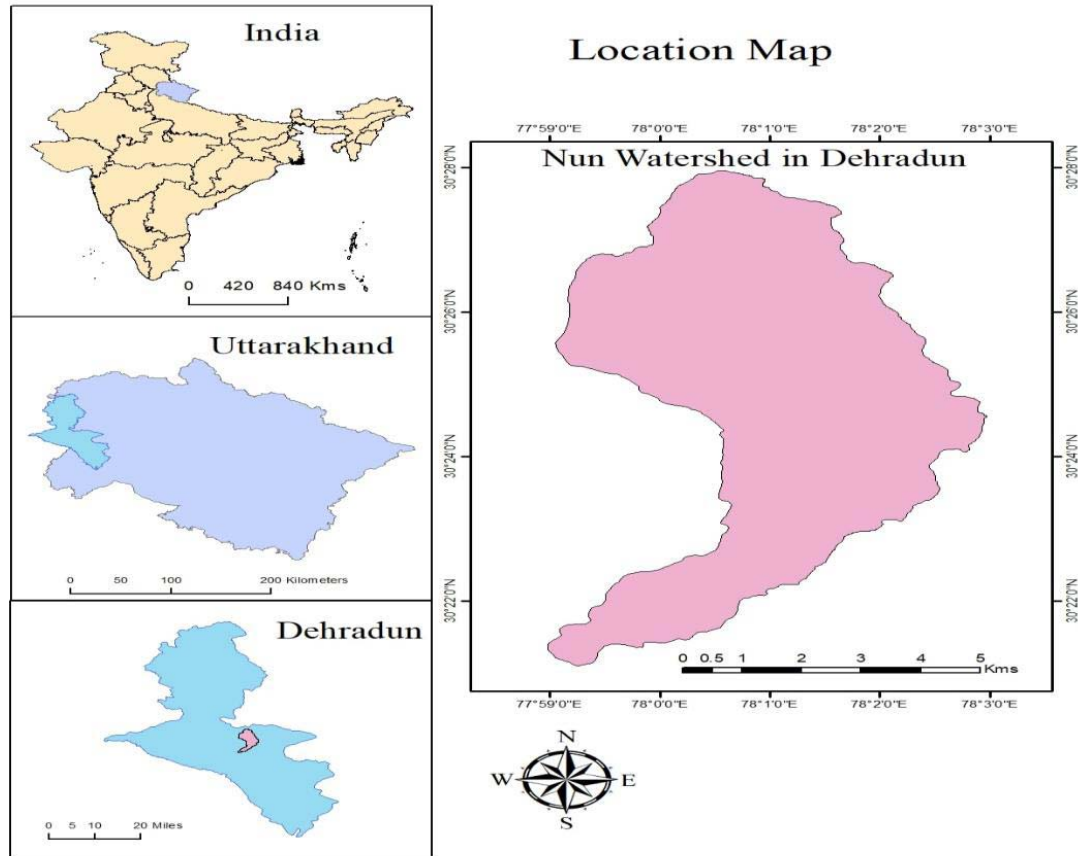

Erosion of soil is complex and universal process. Denudative agents and gravitational force continuously erode the surface of the earth. River is prominent agent in this regards. The most important that affects on soil erosion is water which includes separation, transportation and deposition. Even human activities perform the role in soil erosion. It directly affects on agriculture production. Problem of siltation is burning issue of reservoirs. Estimation and assessment of soil erosion helps to land evaluation. Remote Sensing and GIS technique is a precise tool to analyse the data and to run this model. GIS become very important factor in soil erosion studies. Revised Soil Loss Equation (RUSLE) is widely used in soil erosion studies.

**PHYSICAL SET-UP OF STUDY AREA**

**LOCATION-**

The study area is located in the Deharadun District of Uttarakhand ,India. The district is situated in the foothills of Himalayas, in the north-west corner of Uttarakhand. The Nun watershed occupies an area of 4031 Ha. It is situated at 30021'6''N to 30027'57''N

36 latitude and 77059'9''E to 78025'67''E longitude was selected for the land evaluation  
37 analysis.

38

**PHYSIOGRAPHY :**

41

The watershed area is bordered by the lesser Himalayan ranges to the north and Siwalik to

42

the South. The Study area has different physiographic units like hills of varied slope

43

ranges, upper and lower piedmont. The northern part of study area consists of hills and

44

southern part is of piedmonts.

69

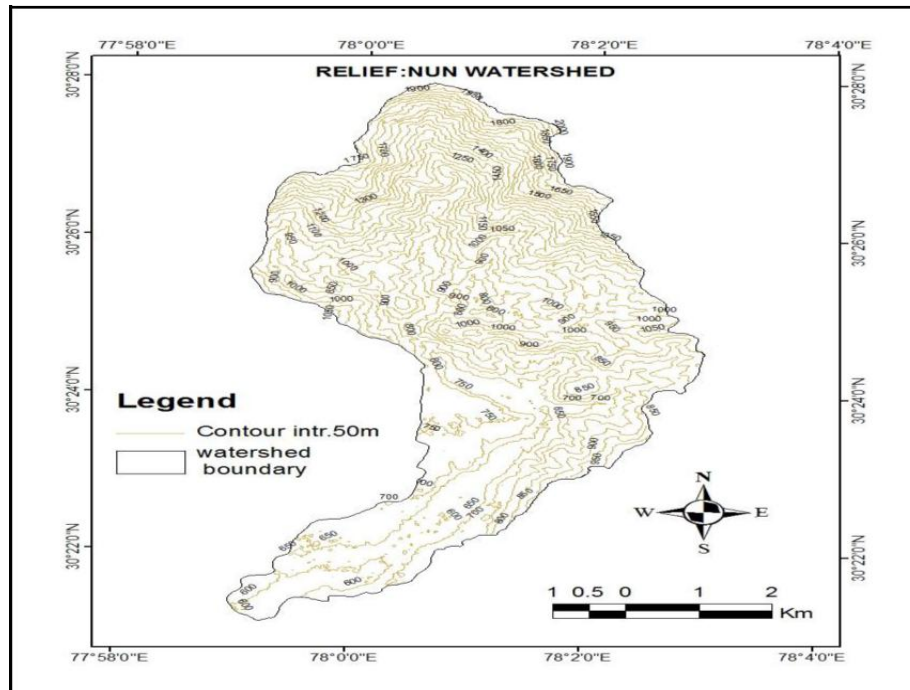

70 **RELIEF :**

71

72 The altitude of watershed area ranges from 480 to 2260 m above mean sea level. The  
73 important peaks area Hattipawan (2160 m ), Bakarna (1081m) and Chhouwala (1093 m ).

74 The relief is represented by 50 m. contour intervals.

75

85

86 *Map No. 3: Relief*

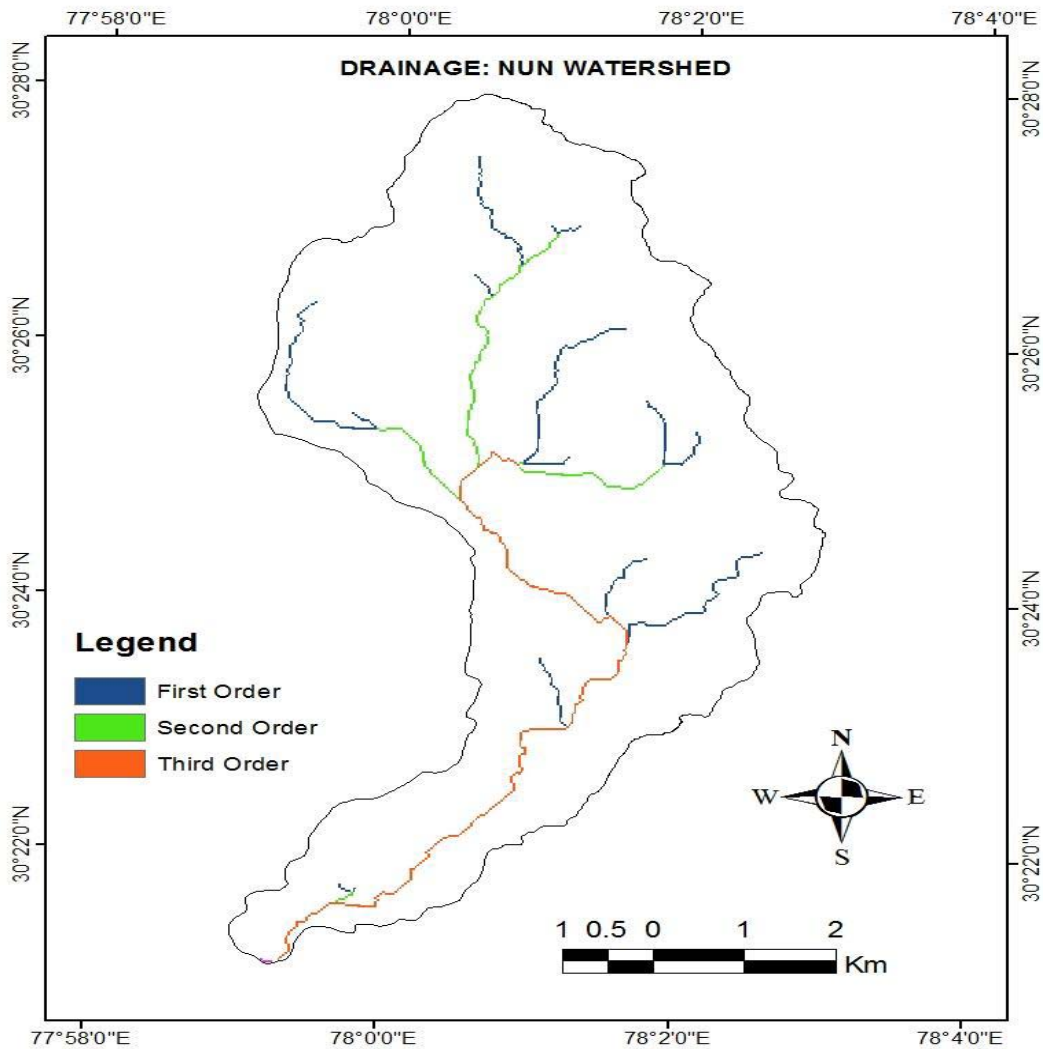

87 **DRAINAGE :**

88 Dehradun district is drained by Ganga, Yamuna and their tributeries. The two basins are  
89 separated by a ridge starting from Mussoorie and passing through Dehradaun. The easterly  
90 flowing river join river Ganga and westerly flowing rivers join river Yamuna. The Nun  
91 River flows from Hattipawan along the north south directions and drains to Tons river near  
92 Bajawala. The Tons river flows westward and confluence with river Yamuna. The length of  
93 the watershed extends 13 km North West.

105

106

**GEOLOGY :**The area of Dehradun is characterized by faults and fractures. The northern boundary of the district is formed by lesser Himalayan range and southern boundary Siwaliks. The Doon valley lies in the Middle and Upper Siwalik. This area is composed of fluvial sediments consisting of conglomerates and sandstone-mudstone complex. The conglomerates are predominantly composed of pebbles and boulders. The debris eroded from the steep slope hills in the northern part, deposits along a shallow longitudinal valley at the foot of the Himalayan range which are formed in the Siwaliks is called “ Doon” The continuous deposits in the valley caused the floor of the valley rise.

1107 **SOIL** :The nature and characteristics of soil play an important role in the growth and  
 1108 development of crops, trees and other vegetation. The soil of the watershed shows large  
 1109 variation due to variation in slope, topography and land use. Due to large variation in relief  
 1110 and slope in the selected watershed, the soils subjected to erosion resulting in wide variation  
 1111 with respect to texture , soil depth, organic matter, stoniness, color, drainage, moisture  
 1112 content and cation exchange capacity. In the northern upper catchment area of watershed,  
 1113 soil depth is less due increased erosion caused by steep slopes and are mostly covered by  
 1114 scrub vegetation . In the upper catchment area, due to very steep slopes, the thickness of the  
 1115 soil is very less and is considered as unproductive. As the slope decreases the soil depth  
 1116 increase and land use change through forest in the lower hills and piedmonts to agriculture in  
 1117 upper and lower piedmonts are seen.

1118 **CLIMATE** :The watershed lies in the subtropical to semi-humid climatic region. The  
 1119 average annual temperature ranges from 30.9 C in summer to 15.2 C in winter with an  
 1120 average annual rainfall of 1700mm. The average annual rainfall during 2004 to 2013 is  
 1121 2344.42 mm . Most of the rainfall is received during the south west monsoon. The months  
 1122 of July and August receive the maximum rains. About 86.9 % of the rainfall is received  
 1123 during monsoon season.

1124 **Table No. 2 : Average Rainfall Distribution (2004-2013 )**

Sr.No.	Month	Average Rainfall (in mm )
1	January	34.86
2	February	103.99
3	March	35.87
4	April	22.82
5	May	56.11
6	June	310.87
7	July	688.62
8	August	362.01
9	September	362.01
10	October	39.57
11	November	4.63
12	December	8.86
	<b>Total</b>	<b>2344.42</b>

1125

126 **DEMOGRAPHY** :As per the Census of India reports, the total population of Dehradun is  
127 5, 78, 420 with male and female population of 303,411 and 275,009 respectively. The sex  
128 ratio of the city is 906 per 1000 male. The number of literates in Dehradun city is 463,791  
129 of which 251,832 are male and 211,959 are female. Average literacy rate of Dehradun city  
130 is 89.32 % whereas male literacy and female rate are 92.65 and 85.66% respectively.  
131 According to topographical map, about 20 numbers of the villages were identified. But out  
132 of 20, only 11 villages were reported by census of India. These 11 census villages are :  
133 Chhoba, Kedderwala, Chandpur (kala and Kurd), Rudarpur, Godrio, Surno, Barwa, Koti,  
134 Dubhal, Kotra ( Kalyanpur, santaup ), Kolwanpur, Birsani with the total population and of  
135 7268, 24 2 ( 224,183), 2136,2116, 1273,270, 651, (666,831 ) ,86 and 352 respectively.

136  
137 **ECONOMY** :The economy of the study area is confined in the agricultural activities. Due  
138 to hilly terrain in the northern part, that tract is beyond any utility. Cultivation in the hill  
139 slope area is of two description, regular and intermittent. The hill, however, contain very  
140 little level ground and therefore, farmers follow terraced cultivation. Intermittent cultivation  
141 consists of small patches of hill sides cleared off shrubs and grass usually by fire.

## 142 **LITERATURE REVIEW**

143 In agriculture, soil erosion is major problem. The deterioration of soil by the physical  
144 movement of soil particles from a particular site is known as soil erosion. Wind, water, ice,  
145 animals, and the use of tools by man in agriculture are usually the main causes of soil  
146 erosion. The soil erosion is a natural process which usually does not cause any major  
147 problems, when its quantity is comparatively low. It becomes a problem when human  
148 activity causes it to occur faster than under normal conditions (Bakkar et al., 2005).

149 Worldwide, farmers are losing an estimated 24 billion tons of topsoil each year. In  
150 developing countries erosion rates per acre are twice as high as the standard, partly because  
151 population pressure forces land to be more intensively farmed. Although soil erosion is a  
152 physical process, it also affects productivity and growth. Reductions in yield of up to 50%

153 have been documented on severely eroded soils in Ontario. When soils are depleted and  
154 crops receive poor nourishment from the soil, the food provides poor nourishment to  
155 people. Losses of soil take place much faster than new soil can be formed. It takes  
156 thousands of years to form just a few centimetres of soil. The difference between creation  
157 and loss represents an annual loss of 7.5 to 10 tons per acre worldwide. The main causes of  
158 soil erosion are still inappropriate agricultural practices, deforestation, overgrazing and  
159 construction activities (yassoglou et al., 1998).

160 Hydrologic and other soil physical properties are particularly important factors  
161 affecting the potential for surface erosion. Coarse-textured soils are low in organic matter is  
162 most susceptible to surface erosion. Most undisturbed forest soils in the region have a high  
163 porosity which, coupled with the low intensity of most rainfall event, seldom result in  
164 overland flow. Prescribed fire and extensive humans developmental activities can increase  
165 soil erosion on steep slopes. Accelerated erosion from human's activity usually has a major  
166 effect on long-term forest and agricultural productivity and may pose severe threat in  
167 future. Therefore it is necessary to assess the risk due to soil erosion by assessing the  
168 quantity of soil eroded from the study area.

169 Keif and Yoshino (2010) has evaluated the economic effects of soil erosion risk on  
170 agricultural productivity using remote sensing. They have carried out the investigations in  
171 the Tunishi watershed. Their results showed that, the erosion risk increases in particular  
172 from mountainous areas to gentle areas and reported the fact that, the erosion risk occurs in  
173 areas with steep slope, poor vegetation, high soil erodibility and no erosion control.

174 The agriculture land is very sensitive for soil erosion as man carries out his most of the  
175 mechanization practices in it for the cultivation and growing of crop plants. Overall humans  
176 activities carried out in agricultural land are acting as an important cause for increasing soil  
177 erosion fro croplands. With this view many researchers are working in these areas. The  
178 impact of the land use on the risk of soil erosion from agricultural lands in Canada was  
179 reported by Shang Li et.al. (2010) and they concluded that, Overall the risk of soil erosion

180 on Canadian cropland was reduced steadily after 1980, because of adoption of conservation  
181 tillage, but till in some agricultural land the risk of soil erosion is there in some crops such  
182 as potato, sugerbeet, corn, soyabean etc.

183 Soil erosion is a physical phenomenon found in nature where surface soil is being  
184 drained from one place to other. The weathering agents, vegetation cover, soil type,  
185 topography of region, and geology of region are acting as an important factors influencing  
186 the soil erosion. Many researchers are assessing the soil erodibility risk in various places by  
187 employing Remote Sensing and GIS technologies. Tingting et al (2008) has assessed the  
188 soil erosion risk in Northern Thailand and reported that, the soil erosion risk is very high in  
189 the altitude between 100 and 400 m zone and it was found lower in forest area as compare  
190 to agriculture and plantation areas. Gitas et al (2009) has assessed the soil erosion risk in  
191 Chalkidiki from Greece by using LISS III data and modified USLE Raster model. They  
192 have modified the protocol for estimation of C and K factors. The USLE factors were  
193 determined as grid layer by processing data and prepared the soil erosion risk maps in three  
194 different seasons and determined its accuracy levels.

195 The result reveals that, the multi temporal NDVI gives better insights than a single data  
196 approach. In modern industrialized era the increase population is degrading the surrounding  
197 environmental parameters and which is posing various kinds of threats. The vegetation  
198 degradation is one of the threat resulted due to human development activities and which is  
199 posing the risk of soil erosion. The increased risk of soil erosion may cause adverse impact  
200 on agriculture as well on horticulture making it unsustainable. Therefore worldwide people  
201 are working on the soil erosion risk of particular areas with respect to deforestation and  
202 other factors in different watersheds. Lu Yuan and Hua Cui (2017) has evaluated soil  
203 erosion sensitivity in Guangxi area by using GIS based system and explain affecting  
204 parameters on soil erosion.

## **MATERIALS AND METHOD-**

To study the soil erosion risk at selected study area of Nun river watershed, the LISS III images of March 2016 was used. The DEM is used to delineate the watershed of Nun River and boundary was determined by employing the following methodology. By using the LISS III the soil erosion from the Nun river watershed was determined by using RUSLE model.

### **RAINFALL EROSION (R) FACTOR:**

The R factor represents the erosive force of a specific rainfall event, The rainfall erosivity is an index of rainfall erosivity which is the potential ability of the rain to cause erosion. To produce R-factor map, the interpolated R- factors were converted into a raster format with 30 m resolution and extracted for the studied watershed.

**The equations for calculation of R-Factor is given below;  $R' = A + 0.329 * DEM$  layer**

$$R = 81.5 + 0.375 * R'$$

### **SOIL ERODIBILITY (K) FACTOR:**

The soil erodibility factor, K value is the rate of soil loss per rainfall erosion index unit as measure on standard plot and often determined using inherent soil properties. The K-factor is related to soil texture, organic matter content permeability, and other factors and it is basically derived from the soil type. K factor is the integrated effect of processes that regulate rainfall acceptance and the resistance of the soil to particle detachment and subsequent transport. Soil textural triangle was used to determine the soil textural class from the percentages of sand, silt and clay in soil.

233

### **SLOPE LENGTH (L):**

L-factor presents the effect of slope length on erosion. Slope length is the distance from the origin of overland flow along its flow path to the location of the either concentrated flow or deposition. In this case study LISS III data and ArcGIS software was used to

238 measure the slope length. Homogeneous field areas were delineated and slope length  
239 measured of many fields and length was generated.

#### 240 **SLOPE STEEPNESS (S):**

241 S factor represents effect of slope steepness on erosion as soil loss increases more  
242 rapidly with slope length. The relation of soil loss to gradient is influenced by density of  
243 vegetation cover and soil particle size. In this case study from SRTM 30 meters data DEM  
244 map was generated from which terrain slope map in degree and percentage was generated.

245

246

#### 247 **TOPOGRAPHIC FACTOR (LS):**

248 The LS factor reflects the effect of topography on erosion where slope length factor (L)  
249 represent the effect of slope length on erosion, and the slope steepness factor (S) reflects the  
250 influence of slope gradient on erosion. The LS factor is considered in the soil loss equation  
251 model due to the fact that both the length and the steepness of the slope substantially affect  
252 the rate of soil erosion by the water. The steeper and longer the slope, the higher is the rate  
253 of erosion by water because of the greater accumulation of runoff. The slope length and  
254 steepness values were drawn from the SRTM DEM (30 m resolution) using the Arc GIS  
255 Spatial analyst tool and the Arc Hydro tool. The resulting slope length (L) map indicated  
256 that the slope length varied from 0 to 102. The slope steepness (S) map showed that the  
257 slope gradient ranged from 07 to 2.46 in the lower and head stream of the watershed,  
258 respectively. Values for combined LS factor varied between 0 and 28.19.

#### 259 **LAND USE/ LAND COVER (C):**

260 The land use/ land cover (C) factor represents the ratio of soil loss from land covered  
261 by vegetation to the corresponding loss from continuous fallow. The C factor is the most  
262 important factor in RUSLE model due to its representation to reduce soil erosion.  
263 Supervised classification was performed to generate land use land cover map. The land use  
264 land cover map has been classified as forest, dense scrub, open scrub, agricultural land,

265 river and settlement. The land use land cover map of the study area was derived from LISS  
266 III image as the basis for determining the C factor values.

267 **CONSERVATION PRACTICE/SUPPORT PRACTICE FACTOR (P):**

268 The P factor is the ratio of soil loss with a specific support practice to the  
269 corresponding loss with up slope and down slope tillage. The lower P value, the more  
270 effective the conservation practice is deemed to be at reducing soil erosion. The  
271 conservation practices (P) factor are also known as erosion control practice factor is the  
272 ratio of soil loss with a specific conservation practice like contouring, strip-cropping, or  
273 terracing measures to the corresponding loss with up and down slope cultivation. Thus, the  
274 P factor for RUSLE can be mapped through by collecting data from frequent field  
275 observations. The P factor ranges from 0 to 1, where the highest value is allocated to areas  
276 with no protection practices.

277 The revised Universal Soil Loss Equation "RUSLE" model aims at predicting soil loss  
278 from lands due to soil erosion by water. This is universally accepted. It is based on 5 factors  
279 related to rainfall (R), soil characteristics (K), topography (LS), land use (C) and cover  
280 management (P).

281 It can be written as;

282  $A=R*K*LS*C*P$

283 Where,

284 A=The annual land loss (ton/ha/year)

285 R = Rainfall erosivity factor ( $MJ\ mm\ ha^{-1}\ IT^{-1}\ yr^{-1}$ )

286 K= Erodibility factor (ton ha hr/ha.MJmm)

287 LS= Slope length and slope indication factor

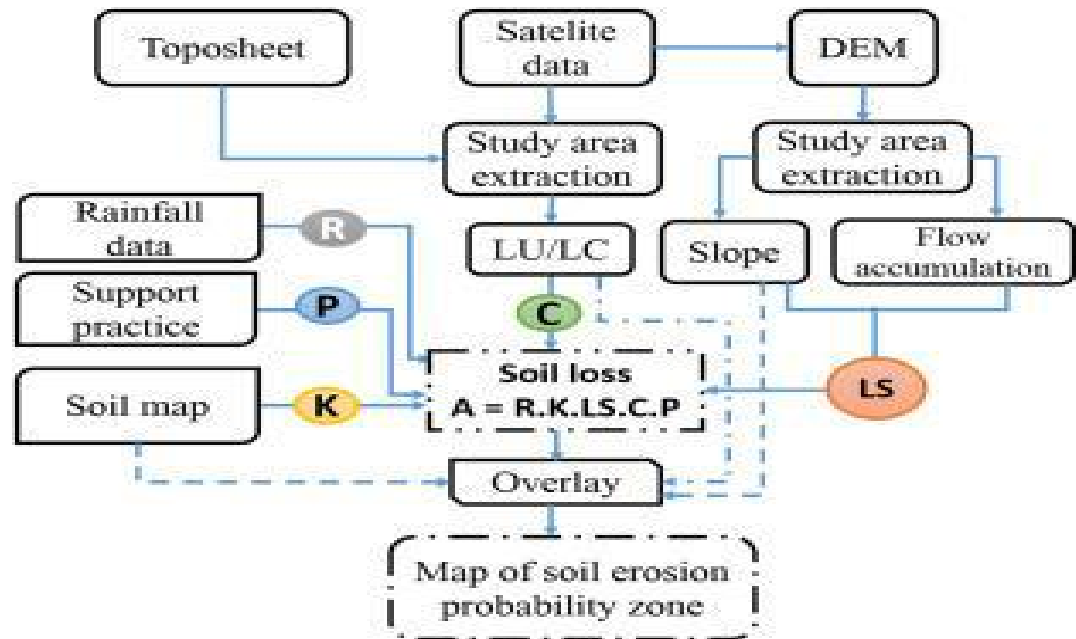

288 C= Vegetation cover Management factor

289 P = Supporting practices factor while' C, P and LS are dimensionless.

290 In this study, these 5 factors are represented on a raster with a cell resolution of 30\* 30m  
291 and geo-referenced to the Universal Traverse Mercator WGS 84 (Zone 44 N). These are

292 computed by using suitable datasets and appropriate software such as ERDAS imagine and  
 293 ArcGIS 10.3

314 **RESULTS AND DISCUSSION:**

315 **Rainfall Erosivity (R) Factor** – The average rainfall of the twenty five years is 2051.4 mm  
 316 and the average annual R factor value varies from 919.74 to 1107.89 MJ ha/mm/hr/yr. The  
 317 mean value is 1013.82MJ ha/mm/hr/yr. The rainfall erosivity was found to be more in the  
 318 northern part of watershed as compared to southern part which is indicative of the decrease  
 319 in the rainfall from north to south and a reflection of spatial variation in erosivity of the  
 320 area.

321

322

323

*Map No. 5: Rainfall Erosivity*

324

325

**Soil Erodibility (K) factor** – The K value in the study area ranged from 0 to 0.07 th MJ<sup>-1</sup>

326

mm<sup>-1</sup> and the mean value is 0.038 th MJ<sup>-1</sup> mm<sup>-1</sup>. The K map show spatial distribution of

327

soil erodibility. It can be seen for the K map that the soil erodibility was found to be higher

328

in the northern part mostly dominated by open scrub.

481 Conservation Practices / Support practice factor (P factor) : The P factor value  
482 varies from 0 to 1 and the mean value is 0.78. From the P map may be inferred that  
483 owing to the hilly topography, majority of the areas in the watershed is engaged in  
484 some conservation practice.

*Map No. 10: P Factor*

**Soil Risk Assessment:** After completing data input procedure and preparation of R, K, C, P and LS maps are data layers, they were multiplied in GIS environment to draw up the erosion risk map showing the spatial distribution of soil loss in study area. The annual soil loss was calculated after obtaining the product of R, K, LS, C, F as factors for soil erosion. The annual soil loss for the Nun watershed varies from 0 to 354 ton/ha/yr. The average annual soil loss is 24.82 ton/ha/yr. Majority of the watershed falls under low erosion risk class excepting few patches in the northern part which is very highly susceptible soil erosion owing to topography and low vegetation. Prevalence of forest cover may account for less susceptibility to soil erosion almost in the entire of Nun watershed.

667

**CONCLUSION:**

668

669

670

671

672

673

674

The study area under taken is a part of Dehradun District, Uttarakhand with an aim to assess the soil erosion risk and model by using RUSLE in the Nun watershed. Remote Sensing and GIS techniques along with field generated data on soil characteristics was used for assessing the risk of soil erosion. From Cartosat 3 30 m DEM, delineation of the study area (Nun watershed) was identified. In this identified study area LISS III image was used to estimate the soil erodibility.

675

676

**The finding of the study shows.**

677

678

- The annual average soil loss of the Doon watershed was found to be 24.82

679

ton/ha/yr.

680

681

- It is clearly evident that the major cause of soil erosion is slope, steepness, heavy rainfall and nature of vegetation cover are influencing the soil erodibility.

682

683

- Highest soil loss was observed in open scrub area followed by agriculture, dense scrub and minimum in forest dominated areas.

684

685 Using RUSLE MODEL, conservation measures can be suggested depending on the  
686 amount of soil eroded from the particular area.
