

Insect pest profile of leaf amaranth (*Amaranthus hybridus* L) in a single organic cropping system and prevention of damage herbivory using oil-based extracts of *Alium sativum* L, *Xylopiya aethiopica* Dunal and *Eucalyptus globolus* L

ABSTRACT

Pest profile of *Amaranthus hybridus* was recorded in a single organic agro-ecosystem in Southwestern Nigeria between November-December in 2016 and January-February 2017, during the dry season. Activities of different pests were monitored to identify those responsible for the most significant damage. OilVegetable oil-based extracts of *Alium sativum*, *Xylopiya aethiopica* and *Eucalyptus globolus* were prepared and applied on *A. hybridus* as protectants against herbivory by phytophagous insects and damage to foliage was were assessed. Thereafter, the extracts were rated based on the mean percentage damage (MPD) recorded in different plots in relation to the treatments. A total of nine pests were recorded from three insect Orders namely, Orthoptera (6362.5%), Coleoptera (1312.5%) and Lepidoptera (25%) (Calculation not 100%) and they were grouped into Major, Minor or Occasional pests based on their activities. Two lepidopterans, *Spoladea recurvalis* and *Psara basalis* (Family: Crambidae) were responsible for the most significant damage. All the extracts reduced damage with statistically significantly difference ($P < 0.05$) compared with the control. The MPD in *X. aethiopica*-, *A. sativum*- and *E. globolus*-treated plots and the control plots were

Formatted: Highlight

24 10.9%, 8%, 14% and 31.2% respectively, when the amaranth was due for harvest in
25 the first trial. The MPD to the amaranth in the treated plots during the second trial
26 was between 13.6% and 16.3% when harvest was due while the MPD in the control
27 was 54.9%. The performances of *E. globolus* and *X. aethiopica* were comparable
28 and they were relatively more effective in protecting *A. hybridus* against
29 phytophagous pest attacks.

30 **Keywords:** *Amaranthus hybridus*, Herbivory, Phytophagous insects, Damage, plant extracts

31 INTRODUCTION

32 *Amaranthus hybridus* is widely cultivated in Nigeria for its edible leaf which contains
33 significant amounts of dietary proteins, vitamins and minerals (Akubugwo et al.,
34 2007). It is well adaptable to the climatic conditions in different agro-ecological zones
35 in Nigeria. In the South West, which is the major production hub, dry season
36 amaranth cultivations are restricted to wetland areas or locations with proximity to
37 water for irrigation. It is a rapid source of income for subsistent and poor-resource
38 farmers because of its relatively short production cycle (14-21 days), simple method
39 of cultivation and high market demands. During the dry season, supply of leaf
40 amaranth often falls short of the demand, the price becomes relatively high
41 (Emokare et al., 2007) and there are periods when amaranth is completely
42 unavailable in the market.

43 Insect pests seriously undermine vegetable production in Nigeria, particularly when
44 they are cultivated for their foliage. Pest density is often high and attacks are severe
45 in the dry season due to relative scarcity of alternative hosts. Amaranth is attacked
46 by a myriad of insect pests in a succession that depends on how long the crop is left
47 in the field (cultivated for leaf or seed) before harvesting. The insect pests that are

48 responsible for the most economic damage to leaf amaranth in the Southwest belong
49 to Lepidoptera and Orthoptera Orders (Joseph et al., 2016; Borisade and Uwaidem,
50 2017a). When leaf amaranth foliage has fully developed, sometimes losses of up to
51 100% can be incurred within one week in pest endemic areas if appropriate pest
52 control action is not initiated.

53 The major Lepidoptera pests of amaranth, *Spoladea recurvalis* and *Psara basal*
54 their eggs on the abaxial parts of early foliage at night, about one week after the
55 appearance of the first foliage, thereby concealing infestation or potential
56 development of pests on the amaranth (James et al., 2010). The eggs hatch into the
57 larvae in about seven to fourteen days, which feed voraciously on the foliage. Major
58 damage often occur between 15-21 days after sowing, although earlier attacks are
59 possible. Apart from the feeding activities that 'skeletonize' the leaves, bulk of the
60 produce is often contaminated with frass and excrements that further reduce quality.
61 *Psara basal* especially produce characteristic webbings on the leaves, which
62 makes the crop completely unmarketable (Borisade and Uwaidem, 2017a).
63 Grasshoppers and Katydid and many other phytophagous insects that move into
64 the field are also responsible for damage.

65 The use of chemical insecticides in vegetable pest management and the unsafe
66 levels of pesticide residues that are left in fresh vegetables are of a serious concern
67 (Akan, et al., 2013). Increasingly and from time to time, chemical pesticides are
68 being reviewed and unregistered for use in the management of vegetable pests,
69 considering their toxicity to non-targets and levels of persistence in the environment.
70 Chemical pesticides may be especially unsafe for pest management in the Nigerian
71 leaf amaranth production system, where the production cycle of 14-21 days is far
72 less than the half-life of the active ingredients in majority of the pesticides in use.

Formatted: Strikethrough, Highlight

73 Chemical pesticides of the Organochloride groups and those containing DDT, which
74 are forbidden in the management of pests in food crops are found in agrochemical
75 retail outlets in Nigeria, and they are being used in the management of vegetable
76 pests by subsistent farmers. Thus, there is the need to reduce dependence on
77 inorganic chemicals in the control of leaf amaranth pests by seeking alternative
78 environment-friendly options.

79 Plants contain organic chemical constituents that protect them against herbivory and
80 disease pathogens and many of these constituents have great potentials for pest
81 management. Garlic (*Alium sativum*), *Xylopia aethiopica* and *Eucalyptus globolus*
82 are widely distributed tropical plants containing extractable bioactive compounds,
83 which have been employed in pest control in different studies (*Ebadollahi*, et al.,
84 2017; Moshi and Matoju, 2017). *Alium sativum* contains alicin, which is repellent or
85 toxic to eggs, developmental stages, and adults of many economic pests (Huang et
86 al., 2017). *Xylopia aethiopica* and *E. globolus* are also known to contain essential
87 oils reported to show repellency, ovitoxicity and adulticidal effects against insect
88 pests (Kouninki et. al., 2007). However, many of the promising evaluations on the
89 use of extracts of these plants for crop protection were limited to ~~store pests~~ in *invitro*
90 bioassays. Efficacy of botanical extracts in field pest management is expected to
91 vary under variable interacting abiotic environmental factors: temperature and
92 relative humidity, often encountered under field conditions. In the field, pests are not
93 confined by limited space, a factor which may become a challenge against plant
94 extracts that are relatively slow in action.

95 Thus, the aim of this study was to record occurrence of pests on *Amaranthus*
96 *hybridus* within a single organic agro-ecosystem in South-Western Nigeria and

Formatted: Strikethrough, Highlight

97 evaluate the propensity of oil extracts of *A. sativum*, *X. aethiopica* and *E. globulus* to
98 prevent damage.

99 **MATERIALS AND METHODS**

100 **Description of experimental site**

101 The study was carried out at Ekiti State University Teaching and Research Farms,
102 Ado-Ekiti, Nigeria (7.6124° N and 5.2731° E), from November to December 2016
103 and repeated between January and February 2017 during the dry season under
104 irrigation system. The study area has an average temperature of 25 °C with wide
105 fluctuations between day and night. The wet season is usually from April –October,
106 with bimodal rainfall pattern which peaks in June and October, while the dry season
107 is from November to March. The study area has a history of severe attacks on dry
108 season amaranth.

109 **Land preparation and experimental design**

110 The land was cleared and plant debris were ~~packed~~ removed before the preparation
111 of beds. The size of each bed was two square meter and a space of 0.5 m was left
112 between the beds. The experiment was a ~~R~~andomized ~~C~~omplete ~~B~~lock ~~D~~esign
113 (RCBD) with three replications. Thus, the field consisted of nine blocks with three
114 beds each, for the treatments and three additional blocks assigned to control. Three
115 other separate blocks were created for the assessment of pest profiles. About 4 kg of
116 poultry manure was spread on each bed and mixed with the top layer of the soil.
117 Thereafter, the beds were irrigated, at least once in two days for a period of ten days
118 to facilitate the decomposition of the poultry manure before sowing. Each block was
119 about 10 m apart to eliminate the influence of a treatment over the other.

120 **Calculation of seed rate**

Formatted: Highlight

Formatted: Strikethrough, Highlight

Formatted: Strikethrough, Highlight

Formatted: Strikethrough, Highlight

Formatted: Strikethrough, Highlight

121 Crop Density, CD (=number of seeds to be sown per square meter) was determined
122 by measuring the weight of seeds equivalent to an estimated value using the
123 proposed formula for standardizing the seed rate of amaranth, (Uwaidem and
124 Borisade, (2017b), here summarized.: $E (g) = \frac{W}{NS} \times \frac{R}{d}$, ? (Where is the equation? It
125 might have been deleted during downloading of the revised manuscript.) where E
126 = Equivalent weight (g), W=Weight of 1 g amaranth seed, NS = Counted number of
127 amaranth seed g^{-1} , R= Required number of plants per bed. One seed of the
128 amaranth used in the current study weighed 0.000441g. Thus, considering an
129 approximate plant density of 500 stands m^{-2} , 0.22 g of the amaranth seeds were
130 sown on each bed.

131 **Sowing and post-planting management**

132 Dry sand was passed through 0.5 mm mesh and 100 g of the fine sand was mixed
133 with the seed for even seed distribution during sowing. A plastic container with a tight
134 fitting lid (100 ml) was modified for sowing the seeds by creating pin-sized
135 perforations (~ 0.5 mm) on the lid. The sand-seed mixture was poured into the
136 plastic and used for broadcasting the seeds. The beds were watered as required
137 using a Watering watering Can can during afternoon periods until the amaranth was
138 due for harvest.

139 **Preparation of vegetable oil-based plant extracts of plants.**

140 Five hundred grams of fresh bulbs of *A. sativum* and dry fruits of *X. aethiopica* were
141 chopped manually using a knife and poured separately into one litre-glass jar with a
142 tight fitting lid. Five hundred ml of vegetable oil was poured into each jar to submerge
143 the contents and kept at -4°C for one hour. Thereafter, the contents of the jar: (*X.*
144 *aethiopica* fruits + vegetable oil) or (*A. sativum* bulbs + vegetable oil) were blended
145 to form an oily paste. Fresh *E. globulus* leaves (500 g) were harvested in the

146 morning and shredded using a knife. The sliced leaves were poured into one litre-
147 glass jar and 500 ml vegetable oil was poured to cover the leaves. The glass jars
148 were transferred into Microwave (Model LG i-wave, MS2021F). Microwaving was
149 done at the Medium-High Power in three 10 minute-sessions, followed by 25 minutes
150 power-off after each session. The oil was separated by vacuum filtration at 4 °C and
151 stored in air tight bottles at 4°C. These were used as the stock plant extract in
152 subsequent assays. **This procedure is wrong for oil extraction.**

Formatted: Not Strikethrough

153 **Assessment of pest profile and nature of damage**

154 Visual survey of insect pests on the amaranth was commenced at six days after
155 sowing and this continued until maturity. Scheduled daily visits to the field was done
156 in the morning (6:00-9:00 am), afternoon (12:00 noon-3:00 pm) and evening (6:00
157 pm-8:00 pm), to scout for insect pests. Insect samples were collected and brought
158 into the Agricultural Entomology Laboratory of the Crop Protection Unit, Faculty of

189 RESULTS

190 Pest profile of *Amaranthus hybridus*

191 The pest profile of leaf amaranth within the single organic agro-ecosystem is shown
192 in **Table 1**. Nine pests from three Orders: Orthoptera, Coleoptera and Lepidoptera
193 were recorded during the first and the second amaranth production cycles. Only the
194 adults of the majority of the Orthopterans, such as the Burrowing cricket
195 (*Velarifictorus micado*), Slant-faced grasshopper (*Orphulella speciosa*), Variegated
196 grasshopper (*Zonocerus variegatus*) and the Green-striped grasshopper
197 (*Chortophaga viridifasciata*) occurred on the amaranth. Their frequency of
198 occurrence was relatively low and they were few in number. Thus, they were
199 classified as occasional pests, causing non-economically important damage in the
200 current evaluation. The nymphs and adults of the Angle-winged katydid
201 (*Microcentrum rhombifolium*), occurred frequently on the amaranth and they were
202 found voraciously feeding on the leaves causing potentially economic damage. It
203 was therefore classified as a major pest. Actively flying adults of two types of moth,
204 *Psara basalis* and the beet webworm moth (*Spoladea recurvalis*) as well as their
205 larvae occurred at all the sampling periods. The adults of these lepidopterans
206 occurred most frequently in the evening while a few **was were** found resting under
207 the leaves during the day. The larvae were voracious feeders and they were
208 responsible for the most significant damage to the leaves (**figure 1**).

209 Assessment of damage and performance rating of extracts.

210 **Table 2**. shows the mean percentage damage (MPD) to the **leafs leaves** of *A.*

225 ***Psara basalís* and *Spoladea recurvalis***

226 the MPD in relation to the extracts as well as the sampling periods. The MPD in the
227 control was significantly the highest in the first and the second trials. At 5 days post-
228 treatment during the first field trial, the MPD recorded in the *X. aethiopica*-, *A.*
229 *sativum*- and *E. globolus*-treated plots were not significantly different, being 4.28%,
230 1.19% and 1.23% respectively, while the MPD in the control plot was 25.37%. The
231 effect of these extracts were also not significantly different in the second trial at five
232 days post treatment (MPD in treatment, 8.49-19.5%; MPD in control=30.69%). At 10
233 days and 15 days post-treatment, the MPD in the *X. aethiopica*-treated plots were
234 not significantly higher, 9.59 % and 10.19% respectively in the first trial. The lowest
235 MPD were recorded in the *X. aethiopica*- and *A. sativum*- treated plots at 15 days in
236 the first trial being, 10.19% and 8.01% respectively and without statistically
237 significant difference. However, significantly higher MPD were recorded in the control
238 at these sampling periods and the values were 31.42% and 54.88% respectively.

239 Based on the pooled values of MPD recorded at the three sampling periods in the
240 two successive trials, the extracts were grouped according to their overall
241 performance using Tukey's Honestly Significant Difference (HSD) (Table 3). The
242 performances of *E. globolus* and *X. aethiopica* were comparable and they were
243 relatively more effective in protecting *A. hybridus* against phytophagous pest attacks.

244

248

249 **DISCUSSION**

250 The study has described the pest profile of leaf amaranth within a single organic
 251 agro-ecosystem, where 63% of the recorded pests were Orthopterans, 25% were
 252 Lepidopterans belonging to the Family Crambidae and 13% Coleoptera. The range
 253 of pests being reported are among those described in earlier studies in other parts of
 254 Southwestern Nigeria (Ezeh *et al.*, 2015; Oke *et al.*, 2015) except the Darkling beetle
 255 which has not been widely associated with leaf amaranth. Leaf amaranth pests
 256 within a single organic agro-ecological region was evaluated in this study and it is
 257 expected that the pest profile of crops in agro-ecological regions that share
 258 resemblances in temperature, humidity, vegetation patterns and cropping systems
 259 would be similar.

260 Biodiversity of insects pests associated with indigenous leaf amaranth species in
 261 Nigeria is increasing (Oke *et al.*, 2015). It is therefore useful to update data on

Formatted: Font: Italic, Font color: Red

Formatted: Font: Italic, Font color: Red

Formatted: Font: Italic, Font color: Red

262 profiles of major vegetable crops from time to time, in order to identify new pests
263 which are getting adapted to new crops. Such data would be clearly necessary in the
264 development of pro-active pest response systems to militate against an outbreak. In
265 many earlier studies, insects were recorded as pests on amaranth by virtue of their
266 occurrence, while the levels of damage caused by each pest was often ignored
267 (Banjo *et al.*, 2003; Oke *et al.*, 2015). The presence of an insect pest on a crop may
268 not adequately indicate its status and justify its classification as economically
269 important under a given cropping condition. The recorded pests in this report were
270 classified into Occasional, Minor, Potential and Major pests using characteristics of
271 damage on the crop (feeding patterns) to identify activities of individual pests or
272 groups and visual evaluation of the levels of damage to establish the severity of
273 attack. It is useful to identify the specific economically important pests that could be
274 potential targets of a pest control programme. However, the status of a given pest
275 may change under different cropping systems, climate and human related
276 environmental perturbations.

277 Incidentally, the insects classified as major pests in this study comprised those
278 breeding on the amaranth. The results suggested that economically important pests
279 of amaranth are essentially those that are capable of breeding on the crop ~~or at a~~
280 ~~proximity to the crop~~ and capable of completing their life cycle or reaching their
281 pestiferous life-stage before the host plant is due for harvest, except where migrant
282 pests are probably involved. Attack on crops can be ~~much~~ ~~very~~ severe when more
283 than one of the life-stages of the pest are responsible for damage, such as the
284 Katydid or when the habit of the pest inflict qualitative damage in addition to
285 quantitative losses caused by their direct feeding. For example, contamination of
286 leaves with frass, webbings and excrements was peculiar to *S. recurvalis* and *P.*

Formatted: Font: Italic, Font color: Red

Formatted: Font: Italic, Font color: Red

Formatted: Strikethrough, Highlight

Formatted: Strikethrough, Highlight

Formatted: Strikethrough, Highlight

Formatted: Highlight

287 *basalis*. Different instar larvae and adults of the two Lepidopterans-*P. basalis* and *S.*
288 *recurvalis* were present, indicating their breeding on the amaranth and they were
289 responsible for the most significant damage whereas, mainly the adults of the
290 Orthopterans and the Coleopteran were found on the amaranth. Similar reports on
291 the pest status of *P. basalis* and *S. recurvalis* showed they are serious pests of leaf
292 amaranth in different agro-ecological regions in Nigeria and other parts of West
293 Africa (James et al., 2010).

294 The oil extracts of the three plants significantly reduced vegetative damage to *A.*
295 *hybridus* compared to the control and the results have demonstrated their potentials
296 for use in the management of vegetable pests at the level of subsistent farming. The
297 method of extraction described is simple, easily transferable and could be adopted
298 by poor resource can farmers. The procedure can also be applied to other plants
299 with volatile bioactive components. The three plant materials contain volatile
300 bioactive substances, which may potentially be lost depending on the method of
301 extraction used. Deep freezing of the plant materials before milling and reduction
302 processes was done to minimize adverse effect of temperature during milling on loss
303 of heat-labile, volatile constituents. Direct blending of the plant materials with
304 vegetable oil was also done to trap oil-soluble volatiles during the milling process.

305 The levels of damage recorded at five days post-application of the three extracts
306 were not significantly different statistically. However, between 5-10 days post-
307 treatment, the MPD increased significantly where *A. sativum* extract was applied.
308 Abiotic interactions (temperature, UV and relative humidity) (Kumar and Poehling,
309 2006) are capable of influencing persistence of organic pesticides rapidly, through
310 their effects on evaporation and chemical decomposition in the field, indirectly

311 affecting overall efficacy. This may be responsible for the increased damage
312 recorded during sampling at 10 days post-treatment.

313 Insect pests are known to locate their hosts through visual and olfactory cues (Bruce
314 et al., 2005) and plant extracts with strong odour may interfere with the capability of
315 pests to accurately locate their targets. However, when the effect of the odour of the
316 plant extracts subside, there are possibilities that more pests would successfully
317 locate their food source. It may also be possible that the extracts were toxic to some
318 of the pests or offered some antixenosis resistance to the plant- that probably
319 diminished over time. More studies are needed in the development of stable
320 formulations capable of yielding consistent results under a dynamic or marginal
321 abiotic influences in the field.

322 The extracted plants; *X. aethiopica*, *A. sativum* and *E. globolus* have been applied
323 into various uses in folk medicine, pharmacy as well as food components (Konning
324 *et al.*, 2004; Tattelman, 2005). Although concentrations of these plant materials that
325 may be toxic to humans are yet to be established and the amounts detectable on
326 treated plants have not been evaluated, they are not expected to cause bio-toxicity
327 or environmental contamination problems when applied on edible vegetables. They
328 can be considered as relatively safe compared with inorganic pesticides.

329 **Conclusion**

330 This study compared the effect of the extracts at a single dose and the MPD to the
331 treated plants over time was used to assess efficacy. More studies are needed to
332 quantify the actual concentrations of bio-active constituents in the plant materials.
333 The effects of the extracts against each of the identified pests need to be studied
334 separately, to evaluate their modes of action, including repellency, toxicity to adults

335 and developmental stages and antixenosis effects. However, the current results are
336 useful primary information in the design of further *invitro* and field studies.
