

Critical Reviews on Engineered Nanoparticles in Environmental Remediation

ABSTRACT

Environmental contamination is one of the important issues that the world is facing today, it is always expanding and leading to grave and harmful effect to the Earth. Nanoparticles have diameter less than 100 nm exhibit new size – dependent properties compared with the bulk material. Engineered nanoparticles (ENPs) have unique characteristics in addition to high surface area -to-volume ratio, which may increase their toxicity relative to bulk materials. Due to high volume production of ENPs products such carbon nanotubes, titanium dioxide, silver, zinc oxide environmental exposure to these compounds is very common. ENPs have their unique properties and applications in the areas of medicine, food& drink, construction, automotive, textiles, energy, electronics, environment etc. Present critical review is focused on recent development of the applications of ENPs in the environmental remediation and their toxic effects.

Keywords: Nanotechnology. Engineered nanoparticles, environmental remediation, carbonaceous materials, metal oxides, zerovalent metals, polymers, semi-conductor devices.

Definition:

According to ISO [1] nanoparticles processes at least one dimension of 1 – 100 nm. Particles have diameter less than 100 nm exhibit new size dependent properties compared with the bulk

21 material. These are several engineered nano materials such as carbon nanotubes,
22 nanocomposites, quantum dots, fullerenes, quantum wire and nanofibers [2]. Nanomaterials are
23 purposely manufactured by humans to achieve the specific characteristics of materials at
24 nanometric scale. Natural nanoparticles are erosion dust or volcanic eruption dust or marine
25 spray. Other nanoparticles produced unintentionally during burning wood or burning diesel
26 engines [3]. Nanotechnology is the creation of materials, devices and systems by controlling
27 matter at the nanometer scale (1 – 100 billionths of a meter).

28 *Classification:*

29 Nanoparticles are mainly classified into four types [4].

- 30 (i) Zero-dimensional (0D) nanostructure: All of the three dimensions are in the
31 nanometric range. Ex. Well separated nano powders.
- 32 (ii) One dimensional (1D) nanostructure: Two dimensions are in the nanometric range
33 and third dimension remains large. Ex. Nanotubes, nano rods etc.
- 34 (iii) Two – dimensional (2D) nanostructure: Only one dimension is in the nanometric
35 range while other two dimensions remains large. Ex. Nano thin films, nano rods etc.
- 36 (iv) Three – dimensional (3D) nanostructure: All three dimensions are outside the
37 nanometric size range. It may consist of group of nano wires, nano tubes, or different
38 distribution of nano particles.

39 Nanoparticles have novel characteristics due to their high surface/volume ratio which make
40 them more reactive than bulk forms of same materials [5]. Living organism required trace
41 amounts of some heavy materials including Co, Cu, Fe, Mn, Mo, Sr and Zn these are
42 essential metals but their excessive levels can be toxic to organism. Heavy metals including

43 Hg, Cr, Cd, As, Pb, Sr are non-essential metals and considered to be great threat for aquatic
 44 life. The iron oxide nano materials have potential nonadsorbent properties in extraction of
 45 these heavy metals from ground water [6]. Fujishima and Konda [7] demonstrated the
 46 potential of TiO₂ semiconductor material to split water into oxygen and hydrogen in photo
 47 electrochemical cell.

48 The TiO₂ band gap is 3.2 eV, therefore UV light ($\lambda \leq 387$ nm) is required. The absorption of
 49 photon excites an electron to the conduction band (e^-_{CB}) generate a positive hole in the
 50 valency band (h^+_{VB}) (Eq.1)

52 The charge carriers can be trapped as Ti³⁺ and O⁻ defect sites in the TiO₂ lattice, or they can
 53 recombine, dissipating energy [7]. Alternatively, the charge carrier can migrate to the catalyst
 54 surface and initiate redox reactions with adsorbates [8]. Positive holes can oxidize OH⁻ or
 55 water at the surface to produce *OH radicals (eq. 2), which, are extremely powerful oxidants.
 56 The hydroxyl radicals can subsequently oxidize organic pollutants with mineralization
 57 producing mineral salts, CO₂ and H₂O (eq. 5) [9]. Electrons in conduction band can be
 58 rapidly trapped by molecular oxygen adsorbed on the titania particles, which is reduced to
 59 form superoxide radical anion (O₂^{*}) (eq. 4) that may further react with H⁺ to generate
 60 hydroperoxyl (*OOH) (eq. 6) and further electrochemical reduction yields H₂O₂ (eq. 7) [10,
 61 11]. These reactive oxygen species may also contribute to the oxidative pathways such as the
 62 degradation of pollutant [eq. 8 and 9] [7, 9, 10]. The photocatalytic reactions mentioned
 63 above expressed as equations.

72 *Applications:*

73 Nanotechnology is fueling a revolution in manufacturing and production, creating new
 74 materials used in variety of different fields, such as cosmetic, pharmaceutical, energy,
 75 catalytic material and environmental applications [12 – 14]. Nanotechnology areas of
 76 applications are summarized in **Table 1**.

77

78

79

80

81

82 **Table 1:** Nanotechnology areas of application:

83	Areas	Applications
84	Automotive:	Lightweight construction; catalysts; Painting; Tires; Sensors; Windshield and
85		body coating
86	Construction:	Materials; insulation; Flame retardants; Surface coatings; Mortar
87	Electronics:	Display; Data memory; Laser diodes; Fiber optics; Optical switches; Filters;
88		Conductive coatings; Antistatic coatings; Transistors
89	Engineering:	Protective coatings for wood; machines; Lubricant-free bearings.
90	Food and Drink:	Packaging; Storage life sensors; Additives; Juice clarifiers.
91	Medicine:	Drug delivery system; Contrast medium; Rapid testing systems; Prostheses and
92		implants; Antimicrobial agents; in body diagnostic systems.
93	Textiles:	Surface coatings; “Smart” clothes (anti-wrinkle, stain resistant, temperature
94		controlled).
95	Chemical :	Filter for paint; Composite material; Impregnation of papers; Adhesives;
96		Magnetic fluids.
97	Cosmetics :	Sunscreen; Lipsticks; Skin creams; Toothpaste.
98	Energy:	Lighting; Fuel cells; Solar cells; Batteries; Capacitors.
99	Environmental:	Environmental monitoring; Soil and groundwater remediation; Toxic
100		exposure sensors; Fuel changing catalysts; Green chemistry.

101 **Household:** Ceramic coatings for irons; Odor removers; Cleaner for glass; Ceramics; Metals.

102 **Sports:** Ski wax; Tennis rackets; Golf clubs; Tennis balls; Antifouling coatings for boats;

103 Antifogging coatings for glasses; goggles.

104 **Military:** Neutralization material for chemical weapons; bullet-proof protection.

105

106 The nanotechnological applications in different environmental areas reported by Mansoori et
107 al. [15] are given in **Table 2**.

108 **Table 2:** Nanotechnological applications in different environmental areas

Type of nanoparticles	Type of treatment	Removal target	Advantage	Disadvantage
Nanoparticles based TiO ₂	Photocatalyst oxidation	Organic pollutant	Non toxicity, water insolubility under most conditions, photo-stability	High operation cost, Hard to recovery, sludge generation
Nanoparticles based iron	Reduction adsorption	Heavy metals, anions, Organic pollutant (dechlorination)	In situ remediation, soil and water treatment, low cost, safe to handle	Hard to recovery, sludge generation, cost for sludge disposal, health

				risk
Nanoparticles based Bimetallic	Reduction adsorption	Dechlorination, Denitrification	Higher reactivity than the iron nanoparticle	Hard to recovery, sludge generation
Nanoclay	Adsorption	Heavy metals, anions, Organic pollutant	Low cost, Unique structures, Long-term stability, reuse, High sorption capacity, Easy recovery, large surface and pore volume	Sludge generation
Nanotube & fullerene	Adsorption	Heavy metals, anions, Organic pollutant	Treatment of pollution from air and water, exceptional mechanical properties, unique electrical properties, Highly chemical stability	High capital cost, low adsorption capacity, hard to recovery, sludge generation, Health risk
Dendrimers	Encapsulation	Heavy metals, Organic pollutant	Simple separation, renewable, large binding capacity, cost-effective, no sludge	Costly

			generation, reduce pollutant to the level of a few ppb, Treatment of pollution from soil and water	
Micelles	Adsorption	Organic pollutant from soil	In situ treatment, high affinity for hydrophobic organic pollutant	Costly
Metal-sorbing vesicles	Adsorption	Heavy metals	Re-use, high selective uptake profile, high metal affinity	
Magnetite & nanoparticles	Adsorption	Heavy metals, Organic pollutant	Simple separation, no sludge generation	External magnetically field are required for separation, Costly
Nanofiltration & nanosieve membranes	Nanofiltration	Organic and inorganic compound	Low pressure than RO	Costly, prone to membrane fouling

109

110 The application of engineered nanoparticles⁹ (ENPs) reported by several researchers [16-21]111 are given in **Table 3**.

112

113 **Table 3:** Applications of Engineered Nanoparticles.

ENP	Applications
-----	--------------

114 **Carbonaceous compounds**

CNTs and their derivatives	Electronics, computers, plastics, catalysts, batteries, conductive coatings, supercapacitors, water purification systems, orthopedic implants, aircraft, sporting goods, car parts, concrete, ceramics, solar cells, textiles
Fullerenes	Removal of organometallic compounds, cancer treatment, cosmetics, magnetic resonance imaging, X-ray contrasting agent, anti-viral therapy

115 **Metal Oxides**

TiO ₂	Sunscreen lotion, cosmetics, skin care products, solar cells, conductive coatings, sporting goods, paints, cement, windows, electronic coating, bioremediation
ZnO	Skin care products, bottle coatings, gas purification, contaminant sensors
CeO ₂	Combustion catalyst in diesel fuels, solar cells, oxygen pumps, coatings, electronics, glass/ceramics, ophthalmic lenses

116 **Semi-conductor Devices**

Quantum dots	Medical imaging, targeted therapeutics, solar cells, photovoltaic cells, security links, telecommunications
--------------	---

117 **Zero-valence Metals**

Zero-valent iron	Remediation of water, sediments and soils to remove nitrates, detoxification of organochlorine pesticides and polychlorinated biphenyls
Nanoparticulate silver	Textiles (e. g., socks, shirts, pants), disinfectant sprays, deodorants, laundry soaps, wound dressings, air filters, toothpaste, baby products (milk bottles, teethers), cosmetics, medical instruments, hardware (computer, mobile phones), food storage containers, cooking utensils, food additive/supplements, appliances (hair dryers, vacuum cleaners, washing machines, refrigerators), coatings/paints
Colloidal elemental gold	Tumor therapy, flexible conducting inks or films, catalyst, cosmetics, pregnancy tests, anti-microbial coatings

118 **Polymers**

Dendrimers	Drug delivery, tumor treatment, manufacture of macrocapsules, nanolatex, coloured glasses, chemical sensors, modified electrodes
------------	--

119

120 Use of graphene for the treatment of greenhouse gases (CO₂, NH₃, SO₂, H₂S and N₂)
121 described by several researchers [22 – 24]. The application of fullerene B40 and fullerene –
122 like boron nitride nano cage for the treatment of greenhouse gases CO₂ and N₂O are also
123 reported by workers [25, 26]. The impacts of nanomaterials, carbon nanotubes [27 – 32],
124 silver nanoparticles [33 – 35], ZnO and TiO₂ nanoparticles [36 – 37] and cerium oxide on
125 human health described by several researchers [38, 39]. Nanoparticles also have several
126 applications in drug delivery [40], imaging [41], sensor [42], blood purification [43, 44] and
127 tissue engineering [45 - 47].

128 Umar et al. [48] has investigated that the simple synthesized α -Fe₂O₃ nanoparticles can
129 effectively be used as efficient photocatalyst for the photocatalytic degradation of organic
130 dyes and effective electron mediators for the fabrication of highly sensitive chemical sensors
131 in aqueous medium. A review summarizes the use of nanomaterials such as zero valent iron
132 (NZVI) and carbon nanotubes (CNT) in environment cleanup like ground water remediation
133 for drinking and reuse, reported by Rajan [49]. Mansouri et al. [50] described various
134 environmental treatment and remediations using different types of nanostructured materials
135 from air, contaminated waste-water, groundwater, surface water and soil. The nanoparticles
136 studies include titanium dioxide, iron, bimetallic, catalytic particles, clays, carbon nanotube,
137 dendrimers, fullerenes and magnetic nanoparticles. Their advantages and limitations in the
138 environment applications are evaluated and compared with each other and with the existing
139 techniques.

140 The use of inorganic, carbon-based and polymeric-based nanomaterials has been
141 demonstrated by Guerra et al. [51]. These researchers have reviewed the use of these
142 nanomaterials for the remediation of different environmental contaminants such as dyes.

143 Organophosphorous compounds volatile organic compounds, halogenated herbicides, heavy
144 metals, chlorinated organic compounds, etc.

145 Li et al. [52] studied engineered superparamagnetic iron oxide nanoparticles for
146 environmental applications. The 8 nm iron oxide nanoparticles were synthesized and
147 transferred into water as stable suspensions by way of an interfacial oleic acid bilayer
148 surface. Once stabilized and characterized, particles-particles and model surface interactions
149 were quantitatively investigated and described as a function of ionic strength, zeta potential,
150 dynamic light scattering and real-time quartz crystal microbalance with dissipation
151 monitoring measurements. The use of metal nanoxides, tungstates and molybdates for the
152 removal of toxic and radioactive species was discussed by Rajkumar [53]. The surface charge
153 of nanomaterials was of great importance as this decided the applications. Antimony
154 phosphate nano ribbons showed a clean separation of uranyl ion from its various mixtures.
155 Nano crystalline manganese oxide was used for the separation of uranium from different
156 metal ions.

157 Patil et al. [54] examined the application of nanoscale zero valent iron, carbon nanotubes and
158 nano-fibers for the remediation of a variety of contaminants including chlorinated
159 compounds, hydrocarbons, organic compounds and heavy metals.

160 Ecofriendly applications of several nanomaterials that have been used in bioremediation of
161 waste and toxic materials have been discussed by Rizwan et al. [55]. Nanomaterials not only
162 directly catalyzed degradation of waste and toxic materials, which is toxic to microorganism,
163 but also it helps enhance the efficiency of microorganism in degradation of waste and toxic
164 materials. This also shows that phytoremediation can be applied in the removal of heavy

165 toxic metal from contaminated soil. This work focused on immense applications of
166 nanomaterials in bioremediation.

167 Khin et al. [56] gives an overview of the applications of nanomaterials in various
168 shapes/morphologies, such as nanoparticles, wires, tubes, fibers, etc. function as adsorbents
169 and catalysts and their composites with polymers are used for detection and removal of
170 gases, chemicals, organic pollutants and biological substances such as viruses, bacteria,
171 parasites and antibiotics. Nanomaterials have better environmental remediation properties
172 due to its high surface area and reactivity. They have developed dendritic nanopolymers for
173 low pressure filtration process to remove perchlorate and uranium from contaminated water.

174 A review on recent development of the commercial available engineered nanoparticles in the
175 environmental remediation and their toxic effects was reported by Kamali et al. [57]. The
176 comparative study of the effectiveness and the toxicity of the engineered nanoparticles for
177 environmental remediation indicated that advanced bimetallic materials such as Fe/Pd, or
178 Fe/Ni can exhibit a better performance in degrading the recalcitrant, environmental pollutants
179 on one hand, and a lower observed toxicity on the other hand. The copper oxides engineered
180 nanoparticles have shown relatively high level of toxicity. Nano zero valent iron (nZVI) is
181 emerging as a new option for the treatment of contaminated ground water. Taghizadeh et al.
182 [58] has given an overview on the characteristics and application of nano zero valent iron and
183 summarizes its use in ground water remediation. The nZVI effectively reduces chlorinated
184 organic contaminants (e.g. perchlorobenzene, pesticides, tetrachloroethylene,
185 perchloroethylene) and inorganic anion perchlorate. The nZVI is more effective at reaching
186 deep zones of contamination, and is more effective at contaminant degradation than iron of
187 larger size.

188 Karn et al. [59] has discussed nanoscale zero valent iron in environmental remediation.
189 Nanoscale Fe particles are effective for the remediation and transformation of a variety of
190 environmental contaminants. No ground water is pumped out for above-ground treatment,
191 and soil is transported to other places for treatment and disposal. Because of the high cost
192 and lengthy operating periods for pump and treat remedies, in situ ground water treatment
193 technologies are increasing.

194 A review on use of nanomaterials for the remediation of environmental contaminants viz,
195 heavy metals, dyes, organophosphorous compounds, chlorinated organic compounds, and
196 halogenated herbicides described by Guerra et al. [51]. This review provides an overview of
197 inorganic, carbon-based and polymeric-based nanomaterials for environmental remediation.

198 Muller and Nowack [60] has described three examples of the use of engineered
199 nanomaterials in soil remediation are nanoscale zero-valent iron for the degradation of
200 halogenated organic compounds, nanoscale calcium peroxide for the destruction of organics
201 (e.g. gasoline) and nanoscale metal oxide for adsorption of metal. The nanoscale zero valent
202 iron is the only application of nanomaterials in soil and ground water remediation that has
203 been successfully commercialized. A short review on application of nanotechnology in the
204 remediation of contaminated ground water was explained by Agarwal and Joshi [61]. The
205 quantitative removal of chlorpyrifos and malathion pesticides achieved by gold and silver
206 nanoparticles supported on activated alumina.

207 Chen et al. [62] presented review which highlights the application of nano zero valent iron
208 (nZVI) in treating refractory compounds. The use of nZVI has some drawbacks such as (i)
209 magnetic attraction between nano iron particles causes the rapid aggregation of particles (ii)
210 nZVI are more prone to react with dissolved oxygen and oxygen rich compounds (iii) nZVI

211 exert some degree of toxicity studies suggest that cell membrane disruption and oxidative
212 stress through the generation of Fe^{2+} and oxidative stress through the generation of Fe^{2+} and
213 reactive oxygen species by nZVI are the main mechanism contributing to nZVI cytotoxicity.
214 These drawbacks overcome by immobilizing nZVI particles on suitable solid supports and
215 also to expand the effective pH range of the Fenton reaction.

216 The nanoparticles made by mechanical and/or microbial action with fundamental building
217 blocks are among the smallest human made objects and exhibit novel physical, chemical and
218 biological properties: which has wider application for detection, prevention, monitoring and
219 remediation of pollutants. This review paper reported by Pandey and Fulekar [63] highlights
220 that nanotechnology offers great promise for delivering new and improved remediation
221 technology to clean up the environment. Present review discussed methods of synthesis
222 (milling of large particle, precipitation of nanoparticles, SCF technology, emulsion and
223 biogenic) size measurements and characterization (TEM, SEM, XPS and XRD etc.) of
224 nanoparticles use of nanoparticles as sensors (Bio, electrochemical, mass, optical, gas) has
225 also been discussed.

226 Firozjaee et al. [64] described a review on application of nanotechnology in pesticides
227 removal from aqueous solutions. The aim of this review is to compile and study current
228 publications regarding pesticides removal by nanotechnology. This study discusses the
229 applications, advantages and limitations various technology processes for removal of
230 pesticides.

231 A review on different management approaches to reduce level of metal contamination in soil
232 and finally to the food chain discussed by Singh and Prasad [65]. The heavy metal pollution
233 is very much concerned because of their toxicity for plants, animals and human being and

234 their lack of biodegradability. The applications of nanoparticles for metal remediation have
235 been attracting great research interest due to their exceptional adsorption and mechanical
236 properties, unique electrical property, highly chemical stability and large specific surface
237 area.

238 Mohamed [66] reported a review on application of nanotechnology in air pollution
239 monitoring. He also gave definition, classification, properties and application of
240 nanoparticles. Air mostly contained pollutants like CO, chlorofluorocarbons, volatile organic
241 compounds, hydrocarbons and nitrogen oxides.

242 Biogenic uranite nanoparticles and their importance for uranium remediation have been
243 described by Bargar et al. [67]. First step in biogenic uranite formation is the reduction of U
244 (VI) to U (IV). Electron transfer presumed to be mediated by C-type cytochromes localized
245 either in the periplasm or on the outer membrane. The second step in biogenic uranite
246 formation entails the precipitation of the mineral. The hydrated biogenic uranite due to its
247 diminutive size, the molecular-scale structure, energetic appear to be similar to those of
248 courser-particles, abiotic, stoichiometric UO_2 . These properties of biogenic uranite
249 nanoparticles make it suitable for the bioremediation of subsurface U (VI) contamination.

250 Adeleye et al. [68] presented review on the performances of traditional technologies and
251 nanotechnology for water treatment and environmental remediation were compared with the
252 goal of providing an up to-date reference on the state of treatment techniques for researchers,
253 industries and policy makers. Case studies were conducted on emulsified zero-valent
254 nanoscale iron for ground water remediation and nanosized silver-enabled ceramic water
255 filters for drinking water treatment. This review submits that nanotechnology is emerging as
256 a promising alternative to traditional methods of water treatment and pollution remediation.

257 The use of iron oxide nanomaterials for the extraction of toxic heavy metals viz. Cd, Cr, As,
258 Pb and Hg from ground water studied by Neyaz et al. [69]. Naturally occurring iron oxide
259 nanoparticles are magnetite (Fe_3O_4), maghamite ($\gamma\text{-Fe}_2\text{O}_3$) and hematite ($\alpha\text{-Fe}_2\text{O}_3$) found in
260 environmental sources such as volcanoes and fires. Metal ferrites such as MnFe_2O_4 , CoFe_2O_4
261 and $\text{Ni Fe}_2\text{O}_4$ can be formed by constituting Fe (II) with the corresponding metal cations. The
262 selection of best method for water purification should follow four conditions (i) Treatment
263 flexibility and final efficiency (ii) Reuse of treatment materials (iii) Environmental
264 friendliness (iv) Low cost. Surface modified iron oxide nanoparticles with various functional
265 groups (like $-\text{COOH}$, NH_2 , $-\text{OH}$, $-\text{SH}$) tend to be a hot research field due to its unique
266 physico-chemical characteristics such as easy and fast separation by applying external
267 magnetic field, chemical inertness, less toxic by-products, biologically safe and
268 biocompatible etc.

269 Buzea et al. [70] conducted studies on sources and toxicity of nanoparticles. Nanotoxicity is
270 now concept to service, present review reveals the results of life long history of evolution in
271 the presence of nanoparticles, and how the human body in particular has adapted to defend
272 itself against nanoparticulate intruders. The key to toxicity of nanoparticles is their minute
273 size, penetrate basic biological structure and disrupt their normal function. The toxic effect
274 included tissue inflammation and cell death. Human have always been exposed to tiny
275 particles via dust storms, volcanic ash, and other natural processes, and that our bodily
276 systems are well adapted to protect us from potentially harmful intruders.

277 The overview of development of nanotechnology in waste water treatment and their adverse
278 effect on human health has been described by Zekic et al. [71]. This overview discussed main
279 nanotechnological processes such as nanofiltration, catalysis, photocatalysis, water

280 disinfection, adsorption of pollutants and nanoscale zero valent iron, the nanomaterials used
281 for water disinfection include chitosan, silver nanoparticles, titanium dioxide, fullerene,
282 carbon nanotubes etc. Present review also described effect of nanomaterials used in
283 wastewater treatment on human health and ecosystem.

284 Nayana and Pushpa [72] has synthesized nanoscale zero valent iron (nZVI) borohydride reduction
285 method for the treatment of wastewater in terms of colour and chemical oxygen demand. The
286 nZVI characterized by scanning electron microscope and particle size analyzer. Batch
287 experiments were carried out under various conditions of pH, dosages and contact time. The
288 COD was reduced to 85% from initial concentration of 9,600 mg/L. The colour was reduced
289 to 55% from initial absorbance value of 0.6596 at 655 nm at a pH of 2.48 at 150 min of
290 contact time and at adsorbent doses of 1.5 g. Colour removal increased with a decrease in
291 pH.

292 The potential for improving the effectiveness of photocatalytic processes by means of
293 semiconductor-metal nanocomposites and merits of combining two advanced oxidation
294 processes was discussed by Kamat and Meisel [73]. Present work described semiconductor
295 nanoparticles as photocatalyst (TiO_2) and semiconductor-metals viz: (Ag, Au, Cu and Pt)
296 nanocomposites for improving the efficiency of photocatalyst. Sensing potential of SnO_2 and
297 ZnO based semiconductor system has also been discussed. The TiO_2 photocatalysis is most
298 useful to degrade polar compounds. When highly polar compounds are formed during the
299 oxidation of organic contaminants, complete breakdown to CO_2 and H_2O is quickly realized.

300 Ruttkay-Nedecky et al. [74] has summarized that the latest findings on the phototoxicity of
301 nanomaterial products based on essential metals used in plant protection. Phototoxicity of
302 nanoparticles may be as a result of the toxicity of substances, which are used for its

303 preparation. The nanoparticles may have potentiating of inhibitory effects on plant growth in
304 different developmental stage. It is concluded from present study that the nanoparticles
305 prepared from essential heavy metals and their oxides have proven to be suitable for use in
306 the agriculture. The least phototoxic of these appear to be nanoparticles made from iron
307 oxides and manganese oxides.

308 The overview of current knowledge of magnetic nanoparticles zero valent iron (nZVI),
309 magnetite (Fe_3O_4) and maghamite ($\gamma\text{-Fe}_2\text{O}_3$) reported by Tang and Lo [75]. This review
310 presented contaminant removal mechanism by magnetic nanoparticles along with factors
311 affecting the ability of contaminant desorption. This review has also discussed aggregation of
312 magnetic nanoparticles, methods for enhancing stability and toxicological effects owing to
313 magnetic nanoparticles.

314 Grieger et al. [76] has discussed environmental benefits and risks of use of zero valent iron
315 nanoparticles (nZVI) for soil and ground water remediation. They have apply a best and
316 worst case scenario evaluation as a first step to quantitatively evaluate the current state of
317 knowledge regarding the potential environmental risk of nZVI.

318 A review on application of nanoscale zero valent iron and its composites for the removal of
319 heavy metal ions from the environment studied by Zou et al. [77]. Present review show
320 excellent removal capacity and environmental remediation of nZVI based materials for
321 various heavy metal ions [Pb(II), Cr(III), Cd(II), As(III), Cu(II), Zn (II), Ni(II), Sb(II)]. A
322 new look on nZVI based materials [nZVI @ $\text{Mg}(\text{OH})_2$, nZVI –KOOL, chitosan based nZVI,
323 bentonite and beta zeolite supported nZVI] and possible interaction mechanism (e.g.
324 adsorption, reduction and oxidation) and latest environmental applications are discussed. The
325 effects of various environmental conditions (e.g. pH, temperature, coexisting cations and

326 oxoanions) and potential problems for the removal of heavy metal ions on nZVI-based
327 materials with the DFT theoretical calculations and EXAFS technology are also discussed.

328 Verma [78] has summarized sustainable synthetic processes developed during the past two
329 decades involving the use of alternate energy inputs and greener reaction media. Titanium
330 dioxide can be doped with metal (Ag) and non-metal atoms such as S, N, C to enhance its
331 activity in visible light. The evolution in the development of “greener processes” continues
332 from solvent-free reactions to the use of alternative energy-input systems, such as microwave
333 or mechanochemical mixing in benign reaction media such as polyethylene glycol and water.
334 The generation of recyclable nanocomposites, especially originating from biomass and waste
335 that is not even consumed by animals (algal and sorghum residues) can be used as agents for
336 the removal or degradation of pollutants and toxins under visible light, thus encompassing
337 several green chemistry principles concurrently.

338 A review on synthesis, structure, sizes compositions and surface properties and applications
339 of bimetallic Fe nanoparticles has been reported by Liu et al. [79]. Reactions between
340 the bimetallic nanoparticles (NPs) and those pollutants categories into four types (i) catalytic
341 replacement reaction for heavy- metal removal, (ii) hydrodehalogenation for halogenated
342 hydrocarbons, (iii) nitro and azo hydrogenation for nitro and azo compounds and (iv)
343 hydrodeoxygenation for oxyanions. The composition for some bimetallic nanoparticles are
344 Fe CO_3 , Fe_2Pt_5 , FePt_3 , $\text{Fe}_{0.6}\text{Au}_2$, Fe Ni_5 , $\text{Fe}_{45}\text{Pt}_{55}$ etc. Compared with monometallic Fe
345 NP's, bimetallic Fe NP's have considerable separability and catalytic ability of degrade
346 nanobiodegradable pollutants.

347 Metal and metal oxide nanoparticles exhibit unique properties such as sorption, magnetic,
348 chemical reduction, ligand sequestration etc. and have separation, catalysis, environmental
349 remediation sensing and biomedical applications. This review on broad coverage of
350 nanoparticles and polymeric/biopolymeric host materials and their properties have been
351 reported by Sarkar et al. [80]. This review also discusses the role of the donnan membrane
352 effect exerted by the host functionalized polymer in harnessing the desirable properties of
353 metal and metal oxide nanoparticles for intended application. Present work is a good channel
354 for the development of new types of hybrid ion exchangers for applications in areas such as
355 heterogeneous catalysis, sensors, health and medicine and drug-delivery.

356 Mukherjee et al. [81] discussed review on the recent developments and approaches made in
357 synthesis of nano zero valent iron (nZVI), structure and characterization of nZVI, challenges
358 faced in the transport of nZVI in the surface environment and the augmentation of the
359 motility of nZVI. They have discussed the effective use of nZVI in remediating organic
360 pollutants (halogenated organic compounds, pharmaceutical waste and azo dyes) and
361 inorganic pollutants (Ni^{2+} , PO_4^{3-} , Co^{2+} , Cu^{2+}). Aggregation of nZVI has been reported to be
362 the major drawback for its applications. The modification of nZVI in order to overcome the
363 challenges faced in the transport of nZVI through the soil has also been discussed.

364 The review focuses on the synthesis, protection, functionalization and application of
365 magnetic nanomaterials (Fe_3O_4 , $\gamma\text{-Fe}_2\text{O}_3$, $\text{Mg Fe}_2\text{O}_4$, $\text{Mn Fe}_2\text{O}_4$, $\text{Co Fe}_3\text{O}_4$, Co Pt_3 , Fe pt) as
366 well as magnetic properties of nanostructured systems reported by Lu et al. [82]. Methods
367 such as co-precipitation, thermal decomposition, micelle synthesis and hydrothermal
368 synthesis are discussed to control size and shape of magnetic nanoparticles. The protection
369 strategies surfactant/polymer coating, silica coating and carbon coating of nanomaterials are

370 also discussed in order to protect them from corrosion. Suitable polymers for coating are
371 includes poly (pyrrole), poly (aniline), poly (alkylacrylates), poly (methylidene
372 malonate) and polyesters such as poly (lactic acid) poly (glycolic acid) and their copolymers.
373 The application of protected nanomaterials in catalysis and biotechnology are briefly
374 reviewed.

375 Kemp et al. [83] investigated a review deals with wide-ranging environmental studies of
376 graphene-based composite material (Fe- rGO, Fe₃O₄, Fe₃ O₄- rGO, M Fe₂O₄ – rGO , Fe C₂
377 O₄- rGO, rGO = reduced graphene oxide) on the adsorption of hazardous materials and
378 photocatalytic degradation of pollutants for water remediation. This review also addressed
379 biological toxicity of graphene applied to environmental remediation. The photocatalyst
380 (TiO₂- rGO, SnO₂ - rGO, CuO - rGO, WO₃ - rGO, Cu- rGO, Au – rGO) for the degradation
381 of organic pollutants are also discussed.

382 The synthesis and applications of magnetic graphene nanocomposites (MGNCS) for the
383 removal of heavy metals (Cr, As, Pd, Hg) from the environment was described by Zhu et al.
384 [84]. Their focus is to reveal potential of MGNCS to reduce the level of heavy metals below
385 EPA requirements. Adsorption behaviour of heavy metals on MGNCS included adsorption
386 kinetics, solution pH effects, concentration effect of both contaminants and adsorbents.

387 Auffan et al. [85] has defined nanoparticles are the particle that has sizes between 1 and 100
388 nm (10^{-9} m) which show properties that are not found bulk samples of the same material.
389 They reviewed the size dependent properties of a variety of inorganic nanoparticles and
390 found that about 30 nm do not in general show properties that could require regulatory
391 scrutiny beyond that required for their bulk counterparts.

392 A review with a set of recommendations for the advancement of understanding of the role of
393 nanoscale silver in environment and ecotoxicological research investigated by Fabrego et al.
394 [86]. Present review summarizes synthesis, characterization and bioaccumulation mechanism
395 of silver nanoparticles. It also present effects of Ag NPs to aquatic organism fish prokaryotes,
396 invertebrates algae and microbes mechanism of toxicity indicated that Ag NPs are more toxic
397 than dissolve silver ion.

398 Bhattacharya et al. [87] have synthesized mixed oxides such as iron-cerium, iron-manganese,
399 iron-zirconium, iron-titanium, iron-chromium, cerium-manganese, thoroughly characterized
400 in sophisticated instruments like SEM, TEM, FTIR, AFM and employed for water treatment.
401 The rapidly growing use of engineered nanoparticles in a variety of industrial scenarios and
402 their potential for waste water purification still have challenge how these nanoparticles can
403 be removed in the water cycle.

404 A review on core/shell nanoparticles: classes, properties, synthesis mechanism
405 characterization and applications described by Chaudhuri and Paria [88]. Core/shell
406 nanoparticles categories as inorganic/inorganic; inorganic/organic; organic/inorganic;
407 organic/organic materials. The choice of shell material of the core/shell nanoparticles is
408 generally strongly depend on the end application and use. The magnetic and fluorescence
409 core materials coated with inorganic materials are extensively studied because of their wide
410 applications in the biomedical and electronics fields. The efficiency of a core/shell
411 semiconductors enhanced by selective coating of core material with higher band gap shell
412 materials. The core/shell has potential of direct use in both imaging and selective drug
413 release.

414 The increasing use of nanomaterials for treatment of ground water results their release in
415 aquatic environment and also their toxic effect to aquatic life nanoparticles are more toxic
416 than larger particle of same substance. Liu et al. [89] present brief summary of technique for
417 nanoparticles removal in water and wastewater but it looks that no treatment can absolutely
418 protect the public from exposure to a large scale dissemination of nanoparticles separation
419 from aquatic environment such as coagulation, electrocoagulation, flotation process, filtration
420 process, biological process, magnetic filtration, capillary electrophoresis etc, are also
421 discussed in the review.

422 Bezbaruah et al. [90] has investigated trichloroethylene (TCE) remediation using
423 encapsulated nanoscale zero valent iron (nZVI) in Ca- alginate biopolymer. Encapsulation
424 expected to offer distinct advances over entrapment. This study has demonstrated that nZVI
425 particles can be encapsulated in Ca – alginate without significant reduction in their reactivity.
426 The TCE removal using encapsulated nZVI was 89 – 91% when compared to 88 – 90%
427 removal using bare nZVI over a 2h period. This TCE degradation followed pseudo first order
428 kinetics for encapsulated nZVI systems. The use of Ca – alginate encapsulated nZVI can
429 overcome the mobility and settlement problems associated with bare nZVI and can be a
430 potential technique for in situ remediation of groundwater.

431 An article on preparation, characterization and application of nanoparticles in
432 preconcentration, separation and determination of trace pollutants from various
433 environmental samples was investigated by Kaur and Gupta, [91]. Nanoparticles are suitable
434 replacement for organic solvent and reactive complexants in the extraction and
435 preconcentration of trace metals and organic compounds from natural water and
436 environmental samples. Chemically modified nanoparticles of silica , titania , zirconia and

437 magnesia with (dithizone , gallic acid , PAN, 8-hydroxiquinilone etc.) are found effective ,
438 highly selective and more efficient for the preconcentration of environmental pollutants .

439 Uzum et al. [92] synthesized nano zero valent iron (nZVI) from borohydride reduction and
440 examined for the removal of aqueous Co^{2+} ions over a wide range of concentrations from 1.0-
441 1000.0 mg/L. The size of nZVI particles was predominantly within the range of 20.0-80.0 nm.
442 Experiment investigated the effects of V/m ratio, concentration, contact time and pH for the
443 removal of Co^{2+} ions. Iron nanoparticles demonstrates very rapid uptake and large capacity for
444 the removal of Co^{2+} ions. X- photoelectron indicate that fixation of Co^{2+} ions takes place through
445 the interaction of their ions with the oxohydroxyl groups on the iron nanoparticle surface in
446 addition to spontaneous precipitate formation on high loading.

447 Synthesis, properties, toxicology and applications of silver nanoparticles was reported by
448 Tran et al. [93]. Transmission of infectious pathogens to the community has caused outbreaks
449 of disease such as influenza (A/H₅N₁), diarrhea (Escherichia coli), cholera (vibrio cholera)
450 etc. throughout the world. This review presented the synthesis and antimicrobial effects of
451 Ag – NPs against various pathogens including bacteria fungi and virus. Some current
452 applications Ag-NPs in water, water – air, surface – disinfection are described. Toxicology
453 considerations of Ag – NPs to humans and ecology are discussed in detail. The future
454 prospects of Ag – NPs for treatment and prevention of currently emerging infections are also
455 discussed. Kharisov et al. [94] has discussed review on iron containing nanomaterials, their
456 synthesis, properties and environmental applications. Attention is also paid to and
457 polymorphic forms of iron oxides and Fe OOH. Greener methods, coated, doped, supported
458 with polymers or inert inorganic materials, core-shell nanostructure of iron oxides and gold
459 was discussed. Water disinfection (against viruses and bacteria), toxicity and risks of iron

460 nanomaterial and applications were examined. This review also described use of iron –
461 containing nanomaterials for the remediation of organic contaminants (chlorine – containing
462 pollutants, benzoic and formic acids, dyes) and inorganic cations Zn(II), Cu(II), Cd(II), and
463 Pb(II) and anions (nitrates, biomates, arsenates) from the environment.

464 Enhanced chitosan/ Fe⁰ – nanoparticles beads for hexavalent chromium removal from
465 wastewater studied by Liu et al, [95]. Fe⁰ nanoparticles (nZVI) were successfully
466 immobilized on epichlorohydrin/chitosan beads (ECH-CS-nZVI beads) for reduction of Cr
467 (VI) from wastewater. ECH-CS-nZVI beads were characterized by SEM and FTIR. The
468 removal of Cr (VI) using ECH – Cs – nZVI beads was consistent with pseudo first - order
469 reaction kinetics. This study demonstrated that SCH –CS – n ZVI beads could become an
470 effective and promising technology for in situ remediation of Cr (VI).

471 The nanoscale zerovalent iron – rectorite (nZVI-R) composite was successfully synthesized
472 through incorporation of nZVI into the natural rectorite as support by Lou et al. [96]. Iron
473 ions were imbedded in the interlayer of rectorite, and then the exchangeable Fe (III) cations
474 were reduced to nZVI by NaBH₄ in solution. Prepared nZVI-R composite material was
475 characterized using XRD, HR-TFM, XPS and XRF etc. In comparison to commercially
476 available nZVI-Junye, nZVI- Lab and Na⁺ rectorite the synthesized nZVI- R composite in
477 this study showed higher decolourization potential for orange (II). The mechanism for nZVI-
478 R in discoloration of orange (II) was postulated by FTIR. The nZVI- R has potential
479 applications in cleaning up environmental contaminants such as organic dyes or halogen
480 compounds.

481 Metal nanoparticles of Au, Ag, Pd and Pt have been synthesized in aqueous media using red
482 grape pomace as a reducing agent and a capping agent described by Baruwati and Verma

483 [97]. The particles are formed within a few seconds when expose to microwave irradiation at
484 a power level as low as 50 W. Particles could be formed at room temperature, but they tend
485 to be amorphous in nature except for gold. A detailed study of the morphology of the
486 ensuring particles with various reaction conditions has been carried out.

487 Nanoscale zerovalent iron (nZVI) became more effective to remove heavy metals from
488 electroplating wastewater when enhances chitosan (CS) beads were introduced as a support
489 material in permeable reactive barriers (PRBS). Investigated by Liu et al. [98]. The SEM
490 images showed that CS – nZVI beads enhanced by ethylene glycol diglycidyl ether (EGDE)
491 had a loose and porous surface with a nucleus – shell – structure. At low concentration (< 40
492 mg/L), heavy metals were removed in order Cd (II) > Cu (II) > Pb (II) > Cr (II). As
493 concentration increased the removal order was changed into Pb (II) > Cu (II) > Cd (II) > Cr
494 (VI). The finding revealed that EGDE – CS – NZVI – beads PRB_s had the capacity to
495 remediate actual electroplating wastewater and may become an effective and promising
496 technology for remediation of heavy metals:

497 Scott et al. [99] reported the effect of vacuum annealing on the structure and surface
498 chemistry of iron nanoparticles (INP). The corrosion resistance and longevity imbued by
499 vacuum annealing of nanoparticles material may prove favourable for applying remediation
500 technologies more effectively in natural and industrial situations. A multidisciplinary
501 approach was used to investigate changes induced by vacuum annealing (< 5 X 10⁻⁸ m bar) at
502 500 °C on the bulk and surface chemistry of INP, in vacuum annealing of INP particle size
503 did not change but surface oxide thickness decreases from 3 – 4 nm to 2 nm. The XRD
504 confirmed that recrystallization of metallic core had occurred converting a significant
505 fraction of poorly crystalline iron to bcc α -Fe and Fe₂ B phases. The XPS indicated a

506 change in the surface oxide stoichiometry from magnetite (Fe_3O_4) towards wustite (FeO)
507 and migration of boron and carbon to the particle surface.

508 A novel biosorbent prepared by the immobilization of phanerochaete chrysosporium with
509 iron oxide magnetic nanoparticles (MNPs) and Ca – alginate by Xu et al. [100]. The
510 structure of prepared MNPs – and Ca – alginate immobilized *P. Chrysosporium* was
511 confirmed by ESEM, EDS, FTIP and XRD characterization. The prepared MNPs – and Ca –
512 alginate immobilized *P. Chrysosporium* was capable of removing Pb (II) ions from solution
513 efficiently, in terms of its performance and cost. Present work provide a potential and unique
514 technique for heavy metals removal by enhanced removal capacity and application stability.

515 Corte et al. [101] reported innovated method for biological synthesis of Pd nanoparticles (bio
516 – Pd). Present review discussed different bio – Pd precipitating microorganisms (*Escherichia*
517 *coli*, *Klebsiella pneumoniae*, *Anabaena*, *Calothrix*, *Clostridium pasterianum*, *Citrobacter*
518 *Braaki*, etc.) and application of catalyst for the degradation of environmental contaminants
519 (e.g. Cr (VI), ClO_4^- , Lindane, Chlorophenol, Trichloroethylene etc.). The microbial scaffold
520 allows a green synthesis of NPs and offers some advantages and perspectives for the
521 development of reactor technologies for metal recovery, soil and water treatment.

522 A short review on application of nanotechnology in the remediation of contaminated ground
523 water was described by Agarwal and Joshi [102]. Present article reviewed status of
524 groundwater quality, basic idea of nanotechnology for remediation and its practical
525 applicability, ongoing projects and future scope of nanotechnology in India. The use of nano
526 zero valent iron (nZVI) in the treatment of chlorinated hydrocarbons and metals from
527 hydrocarbon discussed in the article. The practical applicability of Fe^0 particles lies in the

528 fact to get oxidized into +2 and +3 oxidation states thereby reducing other organic as well as
529 inorganic impurities. The metallic iron (Fe^0) served effectively as electron donor

531 Chlorinated hydrocarbons accept the electrons and undergo reductive dechlorination

533 from a thermodynamic perspective the coupling of the reactions (1) and (2) is often
534 energetically highly favourable

536 The standard reduction potential of ZVI, ($\text{Fe}^{2+}/\text{Fe}^{3+}$) is 0.44 V, which is lower than many
537 organic compounds like chlorinated hydrocarbon and metals such as Pb, Cd, Ni, and Cr,
538 hence these organic compounds and metals are thus prone to reduction by ZVI nanoparticles.

539 Chandhuri and Paria [103] reported an easy synthesis technique a sulfur doped hollow
540 TiO_2 nanocatalyst for photodegradation of organic dye under solar light. The sulfur doped
541 hollow TiO_2 nanoparticles synthesized by template base sacrificial core technique. The
542 photocatalytic potential of synthesized catalyst was tested by degradation of methylene
543 blue dye under solar light. The surface area of synthesized hollow doped nanoparticles
544 comparatively higher ($318.11 \text{ m}^2\text{g}^{-1}$) than TiO_2 particles ($130.94 \text{ m}^2\text{g}^{-1}$) because of the
545 hollow and porous structure, Sulfur doping on TiO_2 decreases the band gap from 3.2 – 2.5
546 eV which make the material more suitable as photocatalyst under solar light. This catalyst

547 can be used effective for environmental remediation purposes because of high surface
548 area and low band gap.

549 The biodegradability of fullerenes, single, double, multi-walled as well as COOH
550 functionalized carbon nanotubes and cellulose and starch nanocrystals in aqueous
551 environment has been investigated by Kummerer et al. [104]. The cellulose and starch
552 nanocrystals are actually better biodegradable than their macroscopic counterparts in aqueous
553 environments whereas fullerenes and CNTS are not at all biodegradable. None of the
554 particles were found to be toxic to micro-organism necessary for oxygen take-up.

555 Gawande et al. [105] has synthesized Fe_3O_4 – cysteine MNPs without any additional source
556 of linkers. The Fe_3O_4 – cysteine, MNPs were successfully used for the synthesis of P-amino
557 carbonyl and hydroquinoline. Magnetic organocatalysts can be easily recovered by simple
558 magnetic decantation and their catalytic activity remains unaltered after nine consecutive
559 cycles making them environmentally friendly and widely applicable due to their efficiency,
560 easy of handling and cost effectiveness.

561 Synthesis, characterization and manipulation of dendrimer – stabilized iron sulfide
562 nanoparticles were studied by Shi et al. [106]. The Fe S nanoparticles were synthesized using
563 ethylenediamine core poly (amidoamine) (PAMAM) dendrimer of generation 4 terminated
564 with amino ($\text{G}_4 - \text{NH}_2$), hydroxyl ($\text{G}_4 - \text{NglyOH}$) and carboxyl ($\text{G}_4 - \text{SAH}$) groups,
565 respectively as stabilizers. Deposition of FeS NPs on to mesoporous silica gel microparticles
566 was confirmed by zeta potential and SEM measurements. Study shows that dendrimer –
567 coated silica particles facilitate the much more effective loading of FeS NPs. The synthesis
568 and manipulation of FeS NPs onto mesoporous silica microparticles provide remediation
569 applications.

570 The potential of nano zero valent iron application for removal of different organic
571 contaminants in different scenario (i. e. ground water, waste water etc.) is studied by
572 Raychaudhury and Scheytt [107]. The reaction efficiencies of nZVI for reduction of nitro
573 organic compounds are found high. The halogenated compounds with high molecular
574 weights or complex structures (i.e. iodinated contrast media, DDT, polychlorinated biphenyls
575 etc.) has showed lower reaction rates with nZVI compared to the widely studied chlorinated
576 hydrocarbons (i.e. trichloroethylene).

577 A review on recent applications nanotechnology is agro-environmental studies with
578 particular attention to the fate of nanomaterials once introduced in water and soil to the
579 advantages of their use and their possible toxicology reported by Mura et al. [108]. Finding
580 show that the use of nanomaterials can improve the quality of the environment and help to
581 detect and remediate polluted sites. It is noted that not all nanomaterials induce toxic effects
582 e.g. TiO_2 , carbon black show low toxicity.

583 Xu et al. [109] investigated review which outline the applications of iron oxide nanomaterials
584 (Fe_3O_4 – silica, flower like iron oxides, hydrous iron oxide MNPs, cysteine coated Fe_2O_3
585 MNPs, amino modified Fe_3O_4 MNPs etc.) for the removal of heavy metals (Cu (II), Cr
586 (VI), As (V), Hg (II), Ni (II) Pb (II) etc.) from waste water. Present review described the use
587 of iron oxide as nanosorbents for heavy metals, organic contaminants, as photocatalyst in
588 photodegradation reactions. The Fe_2O_3 can be applied as a sensitizer for TiO_2 photocatalyst,
589 photo – Fenton like system has been set up with the existence of iron oxides and oxalate. The
590 outlook for potential applications and further challenges as well as the likely fate of
591 nanomaterials discharge to the environment were discussed.

592 A review on application of nanoparticles in agriculture (improving seed germination, plant
593 protection, pathogen detection, pesticide/herbicide etc.) and the role these can play in future
594 agriculture production described by Khot et al. [110]. Toxicity of the ecosystem, potential,
595 residue carried – over in food stuff and nanomaterials phototoxicity are some of the major
596 concerns for the application of nanomaterials in agriculture. There is also need to evaluate
597 the toxicokinetics and toxicodynamics of nanomaterials used for agricultural production.
598 About 1045 residues reported by Food Administration Department (FAD) as pesticide
599 residue, nanomaterial based nanosensors can be used to detect such pesticide residue.

600 Ariga et al. [111] focused especially on materials for environmental remediation based on the
601 concept of materials nano architectonics. Study classified into three categories: (i)
602 Continuous arising problem: Such as removal and degradation of toxic substances including
603 waste due to fossil fuel uses and organic pollutants (ii) Current urgent problem: current
604 emerging topics concerning oil spills and nuclear waste (iii) Breakthrough for future
605 development: advanced method based on supramolecular chemistry and nanotechnology.
606 Toxic substances include removal of fossil waste, degradation of organic pollutants, removal
607 and filtration of other hazardous substances. Current emerging topics included oil spills,
608 nuclear waste, future technology for materials detection include advanced supramolecular
609 systems for sensing. The good knowledge of both basic science and practical usage is
610 required for environmental remediation.

611 Bhuyan et al. [112] investigated biosynthesize zinc oxide nanoparticles from Azadirachta
612 indica for antibacterial and photocatalytic applications. The present work reported low cost,
613 green synthesis of ZnO nanoparticles using 25% (W/V) of neem leaf extract: synthesized
614 nanoparticles characterized by TEM, EDX, XRD, UV-VIS, FTIR. Biosynthesized ZnO were

615 of size 9.6 – 25.5 nm, band gap 3.87 eV and have wurtzite structure. The ZnO nanoparticles
616 have shown good antibacterial (*S. Aureus*, *S. Pyogenes* and *E. coli*) and photocatalytic
617 (methylene blue degradation) activity. Synthesized ZnO nanoparticles found to act as an
618 effective antimicrobial and photocatalytic agent.

619 The biosynthesis of inorganic nanoparticles including metallic nanoparticles (Au, Ag, Hg,
620 CdFe, AuAg, Se, Pt) oxide nanoparticles ($Fe_3 O_4$, $Fe_2 O_3$, TiO_2 , $BaTiO_3$, ZrO_2) sulfide
621 nanoparticles (ZnS , CdS , FeS) and other typical nanoparticles ($PbCO_3$, $CdCO_3$, $SrCO_3$,
622 $CdSe$) described by Li et al. [113]. The biosynthesis of nanoparticles by microbes is taught to
623 be clean, nontoxic and environmentally acceptable “green chemistry” procedure. The use of
624 microorganism (bacteria, yeast, fungi and actinomycetes) classified into intracellular and
625 extracellular according to location where nanoparticles are formed. The applications of these
626 biosynthesized nanoparticles include drug delivery, cancer treatment, gene therapy, DNA
627 analysis, antibacterial agent, biosensors, enhancing reaction rates, separation science and
628 MRI. The main drawback of biosynthesis of nanoparticles are slow process (several or even a
629 few days) instability (nanoparticles formed by microorganism may be decomposed after
630 certain period of time). These two drawbacks need further study.

631 Bi et al. [114] demonstrated that metallic Ag nanocrystals can be selectively formed on the
632 entire surface, edges and partial [100] facets or only edges of simple – crystalline $Ag_3 PO_4$
633 submicro-cubes by simple adjusting the concentrations of ammonia. The photocatalytic
634 performance studies for decomposition of shodamine B indicates that $Ag/Ag_3 PO_4$
635 heterocubes exhibit much higher photocatalytic properties than pure $Ag_3 PO_4$ cubes and Ag
636 nanoparticles under visible light irradiation, which may be due to efficient charge separation
637 at contact interface as well as the enhanced visible light absorption.

638 The effect of alumina nanoparticles on algal growth investigated by Sadiq et al. [115]. The
639 growth inhibitory effect of alumina nanoparticles was observed on both algal species/72h
640 EC_{50} value, 45.4 mg/L for *Chlorella* sp: 39.35 mg/L for *Scenedesmus* sp). Bulk alumina also
641 showed toxicity through a lesser extent (72 h EC_{50} value, 110.2 mg/L for *Chlorella* sp;
642 100.4 mg/L for *Scenedesmus* sp). The concentration dependent decrease in the chlorophyll
643 content is may be due to the shading effect of alumina particles. The FT – IR, optical and
644 scanning electron microscopic images suggest interaction of the nanoparticles with the cell
645 surface. The entrapment of algal cells in aggregates of alumina nanoparticles may play a
646 pivotal role in toxicity to the algal species.

647 Chidambaram et al. [116] develop and apply an efficient biomediation method based on in
648 situ biosynthesis of bio-Pd nanoparticles and hydrogen. The *C. Pasteurianum* BC1 was used
649 to reduce Pd (II) ions to form Pd nanoparticles (bio-Pd) that primarily precipitated on the cell
650 wall and in the cytoplasm. The *C. Pasteurianum* BC1 cells, loaded with bio-Pd nanoparticles
651 in the presence of glucose were used to fermentatively produce hydrogen and effectively
652 catalyze the removal of soluble Cr (VI) via reductive transformation to insoluble Cr (III)
653 species. Batch and aquifer microcosm experiments using *C. Pasteurianum* BC1 cells loaded
654 with bio-Pd showed efficient reductive Cr (VI) removal, while in control experiments with
655 killed or viable but Pd-free bacterial cultures no reductive Cr (VI) removal was observed.
656 The process offers significant advantages over the current ground water treatment
657 technologies that rely on introducing preformed catalytic nanoparticles into groundwater
658 treatment zones and the costly addition of molecular hydrogen to above ground pump and
659 treat system.

660 Silica colloid-polyelectrolyte-iron oxide nanocomposites with both magnetic and catalytic
661 properties have been synthesized via layer by layer assembly by Che et al. [117]. Dynamic
662 light scattering (DLS) and electrokinetic mobility measurements were employed to monitor
663 the evolution of these structures from silica colloid to silica colloid – polyelectrolyte – iron
664 oxide composite. The experiment was conducted to test dyes (methylene blue, methyl
665 orange) removal capabilities of synthesized nanoparticles silica colloid, polyelectrolyte 0
666 functionalized silica colloid (silica PDDA) and silica colloid – polyelectrolyte iron oxide
667 composite (silica – PDDA – IOMMPS). The silica – PDDA – IOMMPS composite is found
668 superior for pollutant removal from aqueous environment mainly due to catalytic property.
669 The finding was rationalized by Langmuir and Freundlich adsorption analysis. The silica –
670 PDDA – IOMMPS nanocomposites hybrid material were remain catalytically active after six
671 months of storage.

672 Khan et al [118] described review for remediation of contaminated soil and ground water by
673 chlorinated organic pollutants (PCB, TCE, TCA, pesticides, solvents), inorganic anions
674 (perchlorates) metal ions [Cr (VI) , Zn (II), Cu (II), Pb (II), Cd(II)] by use nano zerovalent
675 iron . Iron and nickel nanoparticles use for removal of uranium.

676 A report on restriction of nanoparticles in environmental clean up discussed by Snousy and
677 Zawrah [119]. The objective of the work is to point major challenges facing environmental
678 nanoscience and urges developing ecofriendly techniques to ensure good quality of life. The
679 use of nanomaterials in environmental applications requires a better understanding of their
680 mobility, bioavailability and toxicity. This work includes subjects on risk
681 assessment/toxicity, exploring the ecological assessment, toxicity, fate, transport and
682 limitations facing nano zerovalent particles in the ecosystems. Future pollution remediation

683 nanomaterials based techniques may include pollution transport by nanoparticles which will
684 have medical, radiological and national defence implications in terms of human health, safety
685 and the environment.

686 **CONCLUDING REMARKS**

- 687 1. In this critical review applications of engineered nanoparticles (carbonaceous
688 compounds, metal oxides, semi- conductor devices, zerovalent metals, polymers etc) in
689 various environmental remediation areas have been discussed.
- 690 2. The nano zerovalent iron , carbon nanotubes , nanoclay, dendrimers , nanoparticle silver,
691 colloidal elemental gold are found to be an effective tool for removal of heavy metals ,
692 dyes, phenols , organochlorine , organophosphorus etc from the environment.
- 693 3. Carbon nanotubes are found to be a adsorbent for a wide variety of organic compounds
694 from aquatic environment which include DDT , chlorobenzene , chlorophenols ,
695 trihalomethanes ,dyes , pesticides , herbicides , polynuclear aromatic hydrocarbon , p-
696 nitrophenol etc.
- 697 4. The inorganic nanoparticles including oxide nanoparticles (Fe_2O_3 , TiO_2 , ZrO_2 , Fe_3O_4),
698 metallic nanoparticles (Ag, Au, Hg, Pt, CdFe, Se, AuAg) , sulphide nanoparticles (ZnS,
699 FeS, CdS) are found to have well established environmental remediation potential.
- 700 5. There are three main challenges for the production and use of nanomaterials (i) cost
701 effectiveness (ii) impact on human life and environment (iii) use of a particular
702 nanotechnologies.
- 703 6. The nanocatalysts , nanomembranes and and nanoadsorbents are found to be most used
704 nanomaterials.

705 7. The use of nanoparticles in environmental remediation are invariable lead to release of
706 nanoparticles in the environment. The potential risk of these nanoparticles in the
707 environment can be assessed by knowing their bioavailability, toxicity, persistence and
708 mobility. The growing use of engineered nanoparticles in environmental remediation
709 raises question how these nanoparticles can be removed from the environment. This may
710 also be a challenging field of research for relevant researchers.
