EFFECT OF ANTI-TUBERCULOSIS DRUGS ON PATIENTS WITH MULTI-DRUG RESISTANCE TUBERCULOSIS IN MAINLAND HOSPITAL YABA, LAGOS ,Nigeria.

**ABSTRACT**

The occurrence of multi-drug resistance tuberculosis (MDR-TB) among tuberculosis patients has raised global public health concern, especially in Nigeria. The increase in the number of cases of resistance tuberculosis despite the effort and need to curb the menace in Nigeria led to this study. It was a cross-sectional descriptive study of the already confirmed MDR-TB patients at the Mainland Hospital Yaba, Lagos and the aim was to investigate the effect of anti-Tuberculosis drugs on patients with multi-drug resistance Tuberculosis in Mainland Hospital Yaba, Lagos. One hundred self-structured interview questionnaires were randomly administered among already confirmed MDR-TB patients at the hospital to collect bio-data information , and thereafter, received second- line anti-Tuberculosis drugs in phases for 22 months. The patients received the following regimen of treatments based on their weights and ages , the selected regimens administered for 22 months comprised of two phases; first, 8 months of intensive phase of Kanamycin, levofloxacin, cycloserine, prothionamide, and pyrazinamide and second, 12 months of Levofloxacin, cycloserine, prothionamide and pyrazinamide. Post laboratory analysis was used to monitor the effectiveness of the second-line anti-Tuberculosis drugs used. Out of the 92 patients that received the drugs, 89(96.7%) were confirmed negative to MDR-TB , while 3(3.3%) were still positive. The anti-Tuberculosis drugs in the order used is highly recommended for the reduction if not total eradication of MDR-TB in Nigeria. Effort should be geared towards making sure that the MDR-TB patients are confined , proper regimen administered and monitored in order to reduce the rate of spread.

**Keywords:** Drug resistance, Tuberculosis, Patients, Anti-tuberculosis drugs, Lagos.

33

34

35 **INTRODUCTION:**

36 Tuberculosis(TB) is a contagious disease which spreads as a droplet infection and it is the  
37 leading killer of young adults worldwide(1). The world Health Organization declared  
38 tuberculosis a global emergency in 1993 and it remains one of the world's causes of illness and  
39 death (2). Subsequently, multi-drug resistance tuberculosis (MDR-TB) –that is TB resistant to  
40 Isoniazid and rifampicin-emerged as a significant global health concern. Moreover, there are  
41 alarming reports of increasing drug resistance from various parts of the globe which potentially  
42 threaten to disrupt the gains achieved in tuberculosis control over the last decade (3). Beginning in  
43 the late 1940s, antibiotics were developed that were effective in curing TB, however, mutant  
44 strains of TB that were resistant to one or more of these antibiotics began to be identified as early  
45 as 1956 (4). Since then, the evolution of antibiotic resistant among TB has been a growing  
46 problem that is now a major public health threat. As the problem continued to grow, the term  
47 XDR-TB was coined for extensively drug resistant tuberculosis(5) and this is a resistant to at  
48 least four of the first line anti-TB drugs, that is resistance to not only isoniazid and rifampicin,  
49 but also resistance to any of the fluoroquinolones and at least one of the three injectable second  
50 line drugs (Kanamycin, capreomycin, or kanamycin) and is usually associated with HIV co-  
51 infection.

52 In many countries, the extent of drug resistance is unknown and the management of patients with  
53 multidrug resistant –TB (MDR-TB) is inadequate, however, in countries where drug resistance  
54 has been identified, specific measures need to be taken within TB control programmes to address  
55 the problem through appropriate management of patients, adoption of strategies to prevent the  
56 propagation and dissemination of drug resistant TB, since MDR-TB is a man made problem (6).  
57 For instance, in one of the studies where prescriptions of 449 doctors were analyzed, 75% of the  
58 doctors were found to have made some prescription errors (7), also non-adherence to instructions  
59 by the patients and their families.

60 In 2010, the top five countries in terms of total number of MDR-TB cases were India, China,  
61 Russian Federation, South Africa and Bangladesh<sup>8</sup>. Moreso, estimates for the incidence of  
62 drug-resistant TB are difficult to obtain due to insufficient laboratory facilities for drug  
63 susceptibility test in most endemic countries (8). Besides, co-infection with HIV, globally, TB is  
64 also complicated by increasing drug resistance that first developed against the highly effective  
65 first line drugs. An estimated 5% of all TB cases are now MDR-TB and there were  
66 approximately 440,000 new cases of MDR-TB reported for 2008 (9).

67 According to World Health Organization (10,11), Nigeria now ranks 10th among the 22 high  
68 burden countries of TB in the World. Even though TB control and prevention efforts in Nigeria

69 have progressed well over the last two decades of the introduction of Directly Observed Therapy  
70 Short Course (DOTS) strategy, it still constitutes public health challenge (12).

71 Resistance to drugs was reported to have increased from 29.14% to 42.00% between 2000 and  
72 2004 respectively (13), this suggests that though MDR-TB may be poorly documented , it is  
73 likely to have been present even among newly diagnosed patients in Nigeria.

74 In 2011, World Health Organization reported that Nigeria is also among the 4 African countries  
75 with the highest burden of drug resistant TB. Lawson et al (14), in Abuja pilot study , observed a  
76 high co-infection of TB/HIV and 31% of 32 culture positive patients with drug –resistance TB.  
77 Despite TB control, major threat is the emergence of drug-resistant MTB strains, that is  
78 widespread and caused by TB bacteria that are resisitant to two of the first line anti-TB drugs  
79 (rifampicin and isoniazid) (11) .

80 The emergence of drug resistant TB and relatively high burden of HIV/AIDS have impacted  
81 negatively on TB control and prevention efforts in Nigeria. For instance , in 2009, only 24,511  
82 MDR-TB cases were reported to have enrolled for treatment (11) and in 2010, the estimated  
83 prevalence of MDR-TB rose to 650,000 cases among which only 46,000 enrolled for treatment .  
84 Drug treatment is very effective on the condition of strict patients' adherence which may at times  
85 be difficult and prolonged, however, as a result of complexity in taking the drugs, it has been  
86 observed that patients' do not adhere strictly to the instructions on the use of their medication ,  
87 hence, treatment failures, relapse, and the development of drug resistant TB. However,these are  
88 in patients who observe their treatments in an irregular and unreliable way (10).

89 Moreso, extensively drug-resistant tuberculosis (XDR-TB) and multi-drug resistant tuberculosis  
90 (MDR-TB) are immense public health issues and debates are unsettled about how to treat the  
91 patients, what measures need to be taken to reduce the incidence of drug-resistant TB. All these  
92 revelations require urgent need for improving the diagnosis and management of drug resistant  
93 TB especially in resource poor country like Nigeria. It is in line with the above inherent  
94 problems and our utmost concern in the treatment outcomes of resistant tuberculosis that  
95 necessitatd this study.

## 96 **MATERIALS AND METHODS**

97 This study was carried out between February, 2014 and July, 2016 at the Mainland hospital,  
98 Yaba, Lagos. Lagos was chosen because it has a high population density, overcrowded homes,  
99 public places, and transportation with a poor level of personal and environmental hygiene, and  
100 represents an ideal location for the spread of tuberculosis and multi-drug resistant tuberculosis on  
101 the population. And Mainland Hospital Yaba/Ebuta metta as the anchor center because it is a  
102 government owned specialist hospital in Lagos Mainland Local Government Area of Lagos,  
103 located in Yaba and is considered the MDR-TB treatment center, although, solely designed for  
104 the highly infectious airborne MDR-TB disease, also played a positive role in the treatment and  
105 containment of the dreaded Ebola Virus Disease (EVD) spread.

106

107 **STUDY DESIGN.**

108 This is a cross-sectional descriptive study of the already confirmed MDR-TB patients at the  
109 Mainland Hospital Yaba, Lagos, Nigeria.

110 **STUDY POPULATION.**

111 This comprised of 100 already confirmed MDR-TB patients made up of 50 males and 50  
112 females MDR-TB patients at the TB section of the Hospital.

113 **SAMPLE SIZE.**

114 A suitable sample size of already confirmed 100 MDR-TB patients made up of 50 males and 50  
115 females patients at the TB section of the hospital was calculated and randomly selected.

| Categories of respondents | Questionairs administered | Questionairs returned |
|---------------------------|---------------------------|-----------------------|
| Males                     | 50                        | 50(100%)              |
| Females                   | 50                        | 42(84%)               |
| Total                     | 100                       | 92(92%)               |

116

117 Two female MDR-TB patients selected absconded.

118 **SAMPLE SIZE CALCULATION**

119 **Determination of Sample size:** A suitable sample size of one hundred (100) already confirmed  
120 MDR-TB patients were determined using the formula :=  $n=Z^2P(1-P)$

121 -----

122  $d^2$

123 according to <sup>15</sup>, based on prevalence of 7% .

124  $Z=1.96$ (standard statistical level of confidence at (95%)

125  $P=7%$  (population based);  $d=5%$ (precision or margin error);  $n=$ Sample size.

126  $n=(1.96)^2 \times 0.07 (1-0.07)$

127 ----- = 100.03528 = 100.

128 0.0025

129

130

131

132 **ETHICAL APPROVAL AND CONSENT**

133 Permission to carry on with this study at the Mainland hospital was obtained from the ethical and  
134 research committee of the hospital , while verbal informed consent was also obtained from each  
135 of the patients after explaining the reasons behind the study and what they stand to gain.

136 **SAMPLING METHOD.**

137 This was done by random sampling.

138 **STUDY INSTRUMENT.**

139 A structured interview self-administered questionair was designed and used for collection of  
140 information fromt the patients.

141 **POST LABORATORY ANALYSIS.**

142 Post laboratory analysis was used to monitor the effectiveness of the second-line anti-TB drugs  
143 used.

144 The sputa of the MDR-TB patients who received the drugs were analyzed using both culture and  
145 staining methods(Ziehl Neelsen smear microscopic technique and culture 2 lowenstein Jensen  
146 slopes as in NIMER) to monitor the effectiveness or otherwise of the drugs. These were done at  
147 the Nigerian Institute of Medical Research (NIMER) Laboratory, Yaba Lagos .

148 **DATA ANALYSIS.**

149 Statistical analysis was based on simple percentages among related variables.

150 **REGIMEN AND DURATION OF TREATMENT.**

151 Drugs used are Kanamycin, Levofloxacin, Cycloserine, Prothionamide and Pyraznamide.

152 The patients received the following regimen of treatments based on their weights and ages , and  
153 the selected regimen were administered for 22 months in two phases:

154 (a) First 8 months of intensive phase, includes: Kanamycin, Levofloxacin, Cycloserine,  
155 Prothionamide and Pyrazinamide.

156 (b) Second 12 months of continuation phase includes: Levofloxacin, Cycloserine,  
157 Prothionamide and Pyrazinamide.

158 In addition to the regimen, there was proper intensive monitoring, moreso, nutritional  
 159 support to ensure the provision of diet rich in protein and vitmin B6 to prevent  
 160 neurological effects in patients due to Cycloserine/terizidone.  
 161

162 **RESULTS.**

163 Out of the 92 MDR-TB patients that received the drug regimen, 89(96.7%) were  
 164 confirmed negative to MDR-TB.  
 165

166 Table 1: **AGE RELATED RESPONDENTS**

|     | <b>Age range</b> | <b>Frequency(%)</b> |
|-----|------------------|---------------------|
| 167 | Below 20         | 8(8.7)              |
| 168 | 20-29            | 9(9.8)              |
| 169 | 30-39            | 18(19.6)            |
| 170 | 40-49            | 36(39.1)            |
| 171 | 50-59 and above  | 21(22.8)            |
| 172 | Total            | 92(100.0)           |

174 The ages and weights were taken because they are necessary in the administration of anti-TB  
 175 drugs, and the ages that are mostly affected are those in the range of 40-49(39.1%) and 50-59  
 176 and above(22.8%)  
 177

178 Table 2: Respondents marital status

|     | <b>Status</b> | <b>Frequency(%)</b> |
|-----|---------------|---------------------|
| 179 |               |                     |
| 180 | Single        | 17(18.5)            |
| 181 | Married       | 52(56.5)            |
| 182 | Widower       | 11(12.0)            |
| 183 | Divorcee      | 12(13.0)            |
| 184 | Total         | 92(100)             |

---

The table 2 showed that out of 92(100%) respondents , 52(56.5%) were married

Table 3 : Smoking habits

| Smoking      | Frequency(%) |
|--------------|--------------|
| Never smoked | 25(27.2)     |
| Occasionally | 27(29.3)     |
| Often        | 26(28.3)     |
| Very often   | 14(15.2)     |
| Total        | 92(100.0)    |

Table 3 is the pattern of smoking and consequences, occasionally (29.3%) and often(28.3%) smokers had more MDR-TB than the other groups.

Table 4: Alcohol consumption

| Consumption of alcohol | Frequency(%) |
|------------------------|--------------|
| Yes                    | 72(78.3)     |
| No                     | 20(21.7)     |
| Total                  | 92(100.0)    |

Table 4 is the consumption of alcohol and the effects, this result by implication suggests that consumption of alcohol by those who suffer from TB infections is highly risky, because it increases the rate of TB progressing to MDR-TB. And it is important to note that smoking and alcohol consumption has a positive relationship with drug resistance (16,17).

210

211

212

213 TABLE 5: Adherence to prescribed drugs.

|     | Adherence | Frequency(%) |
|-----|-----------|--------------|
| 214 |           |              |
| 215 | Yes       | 83(90.2)     |
| 216 | No        | 9(9.7)       |
| 217 | Total     | 92(100.0)    |
| 218 | <hr/>     |              |

219 Table 5 showed that 83(90.2%) take their prescribed drugs as when due while 9(9.7%) do not.

220

221

222 Table 6 : Reasons for non-adherence(common reasons for non-adherence)

|     | Reasons                       | Frequency(%) |
|-----|-------------------------------|--------------|
| 223 |                               |              |
| 224 | Always forgot                 | 15(16.3)     |
| 225 | Drugs are too expensive       | 40(43.5)     |
| 226 | Poverty                       | 21(22.8)     |
| 227 | Non-availability of the drugs | 16(17.4)     |
| 228 | Total                         | 92(100.0)    |
| 229 | <hr/>                         |              |

230 Table 6 X-rays the factors that militate against the effective treatment of TB infections in  
 231 Nigeria. The cost of the drugs(43.5%) and Poverty(22.8%) were the most potent factors and may  
 232 cause ordinary TB infection to metamorphose to MDR-TB if not checked.

233

234

235

Table 7: Co-habitation

| No of people | Frequency(%) |
|--------------|--------------|
| Living alone | 13(14.1)     |
| Up to 4      | 22(23.9)     |
| 5 and above  | 57(62.0)     |
| Total        | 92(100.0)    |

245 Table 7 is how crowded homes aid in the dissemination of TB and consequently MDR-TB  
246 infections within the environment since this disease is airborne . 62.0% of 5 and above people  
247 respondents live in one room or apartment , 23.9% of up to 4 people of the respondents live in  
248 one room while 14.1% of the respondents live alone .

249  
250

251 Table 8: Post treatment laboratory results.

| Results  | Frequency(%) |
|----------|--------------|
| Negative | 89(96.7)     |
| Positive | 3(3.3)       |
| Total    | 92(100.0)    |

252  
253  
254  
255  
256  
257 Table 8 showed the effect of the anti-TB drugs on MDR-TB patients after receiving the regimen  
258 of the drugs. Out of 92 MDR-TB patients that received the treatments, 89(96.7%) of them with  
259 MDR-TB were confirmed negative, that is had their infections totally taken care of . While  
260 3(3.3%) of the remaining patients were still positive. Therefore, this regimen , if properly

261 harnessed is highly effective against MDR-TB and should be recommended in most of our TB  
262 centers.

263

264

265

### DISCUSSION.

266 The effective treatment of 89(96.7%) of MDR-TB patients out of 92 of them in this study(Table  
267 8) has shown the highly efficacy of combined therapy of second-line anti-TB drugs using 8  
268 months of intensive phase of Kanamycin, Levofloxacin, Cycloserine, Prothionamide and  
269 Pyrazinamide, and 12 months of second continuation phase of Levofloxacin, Cycloserine,  
270 Prothionamide and Pyrazinamide as applied in this investigation, under close monitoring  
271 (Directly Observed Therapy Short Course (DOTS), (7) corroborated this result when he said that  
272 irregularity in taking the drugs, non-monitoring, poverty , non-availability of drugs are some of  
273 the causes of MDR-TB , and is in agreement with Geerligs, (18) who said that MDR-TB is  
274 essentially a man-made phenomenon. According to him , other causes are genetic mutation,  
275 poorly or inadequate administered treatment regimen , short course therapy, poor infrastructure,  
276 unnecessary administrative control on purchases with no proper mechanism on quality control  
277 and bio-availability test, manufacturing of drugs of uncertain bio-availability in fixed doses or  
278 inappropriate drug combinations, poor storage conditions of drugs and substitution by inferior  
279 quality drugs as well as improper diagnosis (7).

280 While MDR-TB is more within the age brackets of 50-59 and above( 22.8%), that of 30-39 years  
281 has 19.6%. Moreover, occasional smokers (29.3%) has the highest portion of MDR-TB , often  
282 smokers has 28.3% followed by never smokers(27.2%), this descending report corroborates the  
283 statement of (16) and (17) who posited that smoking and alcohol are positively associated with  
284 drug resistance . (19) supporting this finding said that smoking, impairs clearance of mucosal  
285 secretion which agreed with (20) who found out that smoking reduces phagocytic ability of  
286 alveolar macrophages which aids in decreasing the immune response and /or CD4 Lymphopenia  
287 due to the nicotine in the cigarettes.

288 Moreso, table 3, showed that alcohol predisposes TB patients to MDR-TB, and is in conformity  
289 with the revelation of (21) who said that alcohol causes alteration in the immune system  
290 specifically in altering the signalling molecules responsible for cytokine production thereby  
291 reducing the active responses and feedbacks of the immune systems. Furthermore, co-habitation,  
292 close contacts/proximity encourages the dissemination of MDR-TB , this correlates the  
293 observation of (22) who reported on the risk of factors of Mycobacterium tuberculosis infection  
294 among children in Greenland.

295 Furthermore, cost of drugs and poverty (table 6) are serious challenges to eradication of MDR-  
296 TB, this is worrisome, laying credence to this assertion are (23), World Health Organization, (24)

297 and (25) who variously reported that Tuberculosis burden follows a strong social economic  
298 gradient between and within countries with the poorest having the highest risk.

299 It is therefore, true that drug treatment is very effective on the condition of strict patient's  
300 adherence which may at times be difficult and prolonged.

301 In conclusion, since MDR-TB is a man-made phenomenon, due to perhaps irregularity in  
302 medication, non-adherence to treatment and others, effort should be geared towards making sure  
303 that the MDR-TB patients are confined, proper regimen administered and monitored in order to  
304 reduce the rate of spread. However, the cost of the drugs, poverty, and non-availability of the  
305 prescribed drugs may be a battle to fight

306 It is therefore imperative that patients using the multi-drug resistant TB drugs should make sure  
307 that their drugs are used regularly as prescribed, there should be proper public information by the  
308 government agencies on health about people managing the TB, what to do and the signs, causes  
309 and implication of MDR-TB. Again TB patients should always go for proper medical laboratory  
310 diagnosis, government should continue to subsidize and monitor the drugs for the TB patients,  
311 early information is paramount as it is an effective factor in managing MDR-TB. And DOTS and  
312 DOTS-plus TB programs should be integrated with well functioning HIV management programs  
313 to ensure that Anti-Retro-virals are widely administered to limit susceptibility to TB disease.
