MALARIA VECTOR ABUNDANCE AND THE INCIDENCE OF MALARIA PARASITEMIA AMONGST STUDENTS LIVING IN NNAMDI AZIKIWE UNIVERSITY HOSTELS

MALARIA PARASITAEMIA AND ITS VECTOR ABUNDANCE AMONGST STUDENTS IN NNAMDI AZIKIWE UNIVERSITY HOSTELS

Comment [SSL1]: I SUGGEST THIS TITLE

ABSTRACT

Comment [SSL2]: It is important to give a brief (max two lines) background on your study in the abstract section before jumping into objectives.

Comment [SSL3]: Main goal or main aim

Comment [SSL4]: How many months of survey please be clear? Avoid contracted statements.

The major intent of the study was to determine the prevalence of malaria parasitemia and the abundance of malaria vectors in and around the university hostels. The study was carried out in school hostels of Nnamdi Azikiwe University, Awka between March through September, 2018. A total of fifty (50) rooms, from five (5) different blocks were sampled. One hundred and fifty (150) students were tested for malaria parasitemia. Questionnaires on the frequency of clinical symptoms and signs of malaria as well as net ownership and usage were distributed to the students. Indoor resting mosquitoes were collected from the fifty (50) rooms through pyrethrum knockdown and larval survey was also carried out for the immature stages of mosquitoes. Data were analyzed statistically for significant differences using the Chi-square test. Of the 150 students examined for malaria parasitemia, 135 (90%) showed positivity to the parasite. Out of the infected population, 122(90.4%) had a low intensity of malaria infection, 13 (9.6%) had a medium intensity while none of them had a high intensity of the infection. Two hundred and twenty three (223) mosquito larvae were collected from their breeding habitats and one hundred and ninety three (193) adult mosquitoes of different species were collected indoors. Although there was no significant difference existing between the number of rooms sampled and the number of mosquitoes collected at 5% level of significance ($\chi^2_{tab} > \chi^2_{cal}$; $9.488 > 6.307$). From the questionnaire shared to the 150 students, 30 (20%) of the students treat malaria every 3 months, 20(13.3%) every 6 months, 24 (16%) before resuming school, 76(50.7%) only when they develop clinical malaria. On possession of insecticide treated net, 81 (54%) of the students have insecticide treated net, while the remaining 69 (46%) students did not. In conclusion, sensitization and implementation of the use of long lasting Insecticidal Nets (LLINs) by the students will go a long way in reducing the prevalence of malaria as the practice kills the malaria vector and effectively reduce the chances of effective malaria transmission by the vector

Comment [SSL5]: Please this statement does not educate me on which test was used to compare which parameters. If you cant make it clear in the abstract then avoid signalling stat tests here and detail it in the materials and methods section of the MS.

Comment [SSL6]: Past tense

Comment [SSL7]: Check tense

Keyword: Malaria, *Anopheles gambiae* sl, LLINs

Introduction

36 Malaria remains an important public health disease in both tropical and subtropical countries of
37 Africa where transmission is principally through the bite of an infected female *Anopheles* mosquito
38 (1). Transmission rarely occurs through direct inoculation of infected red blood cells through blood
39 transfusion, congenital transfer or sharing of needles (2).

40 The degree of malaria prevalence in any area is determined by species of indigenous anopheline
41 mosquitoes, their relative abundance, feeding, resting behaviour and the suitability of human host to
42 *Plasmodium*, among others (3).

43 The control of malaria is becoming increasingly challenging in many developing areas of the world
44 including Nigeria as the parasites as well as their vectors have shown resistance to anti malarial drugs
45 and insecticides in various part of the country (4, 5).

46 The government has been committed to malaria control by intensifying the malaria awareness
47 campaign, emphasizing prevention and eradication of malaria using effective malaria control
48 programme for pregnant women and children of pre-school age (6). This control programme has not
49 been extended to the tertiary institutions of learning as the disease is known to have a negative
50 impact on performance of students (7). As expected, students absent from lectures for one week or
51 more over a semester due to malaria parasitemia have a higher possibility of poor school
52 performance than those who were absent for less than one week. School absenteeism may lead to
53 loss of knowledge provided in the lecture hall, leading to students academically lagging behind other
54 students in the same class. The use of both free or subsidized chemotherapy and insecticide treated
55 nets (ITNs) have not been extended to the academic communities which represents a considerable
56 size of the Nigerian youths.

57 The major intent of the study is to determine the prevalence of malaria parasitaemia and the
58 abundance of malaria vectors within the various locations in and around the university hostels.

59

60 STUDY AREA

61 The study was carried out in the school hostels of Nnamdi Azikiwe University, Awka, Awka-South
62 local government area of Anambra state between March through September, 2018. The climatic
63 condition during the study period created favourable breeding sites for *Anopheles* species which are
64 the known vectors of *Plasmodium* parasites. The study area and its environs house mainly the
65 students and workers in Nnamdi Azikiwe University, Awka. The students live mainly in hostels
66 which are partitioned in blocks.

Comment [SSL10]: Anti-malaria

Comment [SSL11]: Cite the study of Bamou R & Sevidzem SL. 2016. ABO/Rhesus blood group systems and malaria prevalence among students of the University of Dschang, Cameroon. Malaria World Journal, 7:4.

This study was carried out at the University level to assess the level malaria prevalence amongst students.

Comment [SSL12]: Main aim

Comment [SSL13]: tense

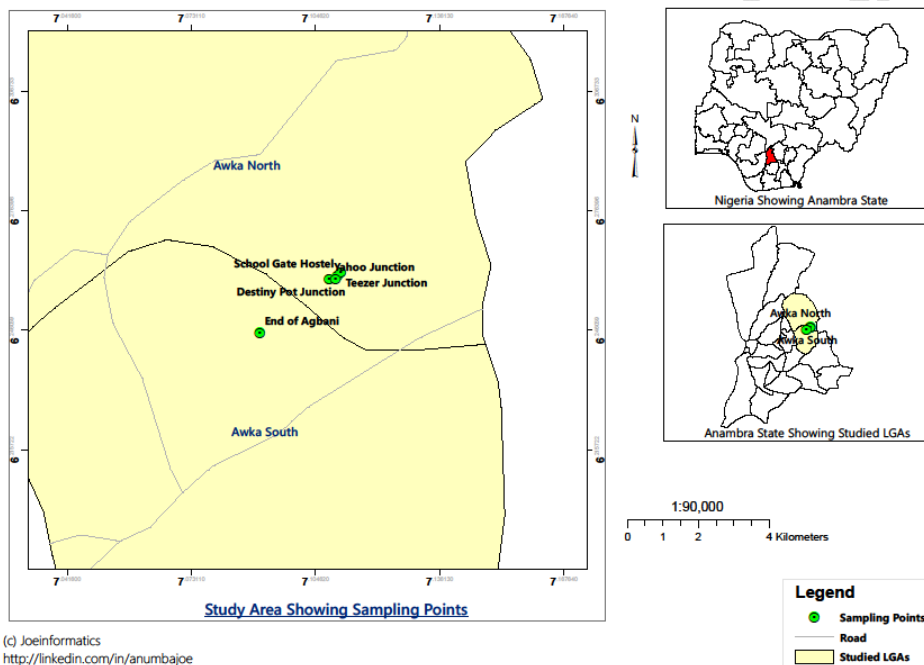

Comment [SSL14]: Place the map and GPS points under the study area heading and not under study population.

70

71

72 STUDY POPULATION

73 The participants in the study were students of the University living in the school hostels in Agbani-
74 Ifite. The participants were of various ages ranging from 17 to 30 years. A total of fifty (50) rooms
75 were sampled from five (5) different blocks of the selected twenty five (25) hostels in the settlement.
76 One hundred and fifty (150) students were tested for malaria parasitemia and the fifty (50) rooms
77 were also sampled for indoor resting mosquitoes.

78
79 Figure 1: Map of the study site

80

81

82 Ethical Consideration

83 Ethical approval was obtained from the Dean of the Student Affairs and Head of Department
84 Parasitology and Entomology, Nnamdi Azikiwe University. Verbal consent was obtained from the
85 occupants of all rooms used. Provision were made to contain students who may be absent on the
86 supposed testing date.

87

88

89
 90 **SAMPLE & DATA COLLECTION**
 91 Samples were collected from five different locations using the school (Nnamdi Azikiwe University)
 92 as stand point: Landmarks of the location of the hostels were listed in terms of the junctions closest
 93 to the hostels while the geographical coordinates used were for the particular hostels used for the
 94 study.

Comment [SSL15]: What sampling method was used to select participants? Randomly or only volunteers? Please it is important to specify.

96 TABLE 1: SAMPLE COLLECTION POINTS

LOCATIONS	DESCRIPTION	LANDMARK	GEOGRAPHICAL CORDINATES
Location A	(Hostels before the school)	Commissioner's quarter Ifite	06.2459N, 007.0997E
Location B	Hostels in front of the school)	Yahoo junction	06.2590N, 007.1080E
Location C	(Hostels after the school)	Teezer junction	06.26067N, 007.1109E
Location D	(Hostels farther down the school)	Next level junction	06.2608N, 007.1108E
Location E	(Hostels at the end of Agbani-Ifite).	St Stephen's junction	06.2665N, 007.1202E

97
 98 Mosquito samples were collected using the pyrethrum spray sheet collection (PSC) technique and
 99 larval sampling while blood samples collected from the students were tested for malaria parasite.
 100 Questionnaires were used to collect the bio-data and clinical details of the participants.

Comment [SSL16]: From all the students of the study blocks or volunteers? Please specify the nature of your participants.

102 **Collection of blood samples and film preparation**

103 Capillary blood samples of the participants were collected aseptically with a lancet and were used to
 104 make thick blood films on clean grease free slides. The prepared blood films were properly labelled
 105 as recommended by the World Health Organization (8). Safety precautions were adopted in the
 106 collection of finger-prick blood samples by swabbing the area to be sampled with 70% alcohol and
 107 allowed to air dry before collection.

109 **Staining and microscopy**

110 With the air-dried blood smear placed on the staining rack, 10% Giemsa stain was poured generously
 111 on the slide. The stain was allowed to stay for 10minutes before washing it off with clean water.

Comment [SSL17]: Poor technical term please re-word

112 The slide was then placed vertically and allowed to air dry. When dried, a drop of immersion oil was
113 placed on the slide and examined under the microscope using x100 objective.

114 The intensity of malaria was recorded using the plus sign thus:

115 Mild infection (+): 1-10 parasites per 100 high power fields;

116 Moderate infection (++) : 11-100 parasites per 100 high power fields;

117 Heavy infection (+++) : 1-10 parasites per high power field (8).

118

119 **Mosquito larval collection**

120 Larvae from different locations were collected and put in separate sampling containers. Collected
121 samples were differentiated based on certain macroscopic features such as their movements and the
122 presence or absence of siphon. They were allowed to emerge into adult in a cage and then identified
123 properly.

124

125 **Collection of indoor-biting mosquitoes**

126 Enumerated hostel rooms were sampled for indoor biting and resting adult mosquitoes using the
127 pyrethrum knockdown technique. White sheet of cloth were laid from wall to wall and were made to
128 overlap with each other at the centre of the room to avoid escape of knocked down mosquitoes. The
129 rooms had no open eaves and so the windows and doors were properly shut for each room at the
130 sampling time. The rooms were sprayed with Insecticide (Raid^{TR}), a brand of domestic aerosol
131 insecticide commonly available in the local markets. After 20 minutes of spraying each room, the
132 doors and windows were opened and the cloths were folded. Folding of the cloths was from the
133 edges to ensure that all knocked down mosquitoes concentrated at the centre. They were then taken
134 to the open space outside where they were opened. All the mosquitoes were carefully picked with
135 forceps into Eppendorfs tubes. The collected mosquitoes were mounted on glass slides and viewed
136 under microscope for identification using relevant taxonomic keys (9). Morphological feature of the
137 mosquitoes such as, palps, proboscis, wings, scutellum, legs, thorax, abdomen, size and colour were
138 used to identify the adult mosquitoes (10).

139

140 **Administration of questionnaires**

141 Structured questionnaires were given to the selected students of the various sampled hostels to
142 provide information on how often they treat malaria, the drugs and insecticide used in the treatment
143 of malaria and prevention of mosquito bite respectively, if self treatment and confirmatory testing is
144 practiced, and what factors determine their choice of drugs as well as their use of interventions such
145 as insecticide treated nets.

146

147

148

Comment [SSL18]: What was the type of identification used? If it was morphological identification please cite the key that was used.

149 **DATA ANALYSIS**

150 Data from the prevalence study were analyzed statistically for significant differences using the Chi-
151 square test. [Tables, bar charts and pie charts were used for descriptive analysis of the results
152 obtained.]

Comment [SSL19]: Not important

Please specify the statistical package used for analysis and the level of significance of the statistical test uses.

154 **RESULTS**

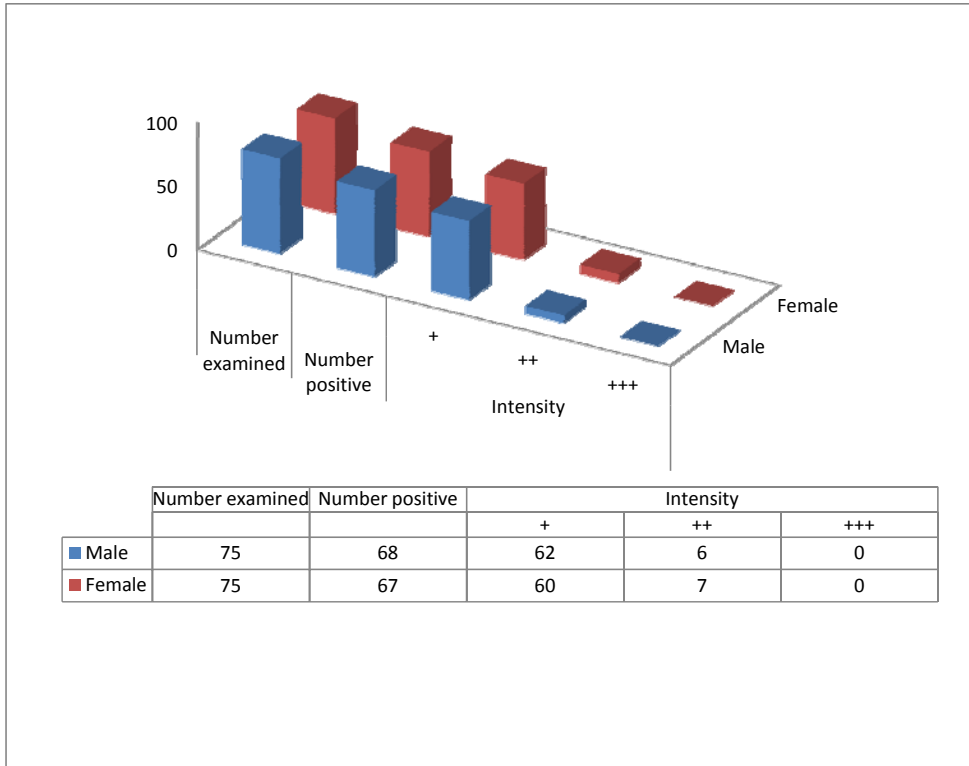

155 Of the 150 students examined for malaria parasite, 135 (90%) of them showed positive peripheral
156 blood film for malaria parasites. The students living at Location E recorded the highest prevalence of
157 100% followed by students living at Location C, and then students at Location D. The students living
158 at Location A recorded 86.7%, while those living at Location B recorded the least prevalence of
159 malaria infection (76.7%). The difference in prevalence of malaria in the various locations was
160 statistically significant at 5% level of probability ($\chi^2_{cal} > \chi^2_{tab}$; 16.88 > 9.488)

162 TABLE 2: PREVALENCE OF MALARIA INFECTION IN DIFFERENT LOCATIONS

Locations	Numbers examined	Numbers infected (%)
Location A	30	26 (86.7%)
Location B	30	23 (76.7%)
Location C	30	29 (96.7%)
Location D	30	27 (90.0%)
Location E	30	30 (100%)
Total	150	135 (90%)

163
164 Prevalence of malaria among the different sexes showed that of the 150 students (75 females and 75
165 males) examined, more males (68) than females (67) had the malaria parasite. Although there is no
166 statistical significant difference between prevalence of malaria infection among males and females at
167 5% level of significance ($\chi^2_{tab} > \chi^2_{cal}$; 3.841 > 0.0473)

168

169

170 Figure 2: Prevalence and intensity of malaria parasite among the sexes

171 Of the infected population (60 females and 62 males) had a low intensity of malaria infection, seven
 172 females and six males had a medium intensity while none of them had a high intensity of the
 173 infection.

174 On the three consecutive visits, a total of two hundred and thirty three (233) mosquito larvae were
 175 collected from their breeding habitats which includes: pot holes, stagnant water, gutters,—hoof marks
 176 and tyre marks from different locations, one hundred and forty five (145) *Anopheles gambiae sl* were
 177 collected from natural pools of water and eighty eight (88) were of *Culex species*

178

179

193 TABLE 4: INDOOR RESTING ADULT MOSQUITOES COLLECTED IN THE HOSTEL USING
 194 PYRETHRUM KNOCKDOWN COLLECTION (PKC)

Locations	Number of room	Number of mosquitoes	Mean <i>Anopheles</i> abundance	Species of mosquitoes collected		
				<i>An gambiae</i> sl	<i>Cx quiquefasciatus</i>	<i>Mansonia africana</i>
A	13	36	0.3	4(11.1%)	32(88.9%)	0 (0%)
B	13	30	0.8	8(26.7%)	22(73.3%)	0(0%)
C	12	54	1.4	17(31.5%)	37(68.5%)	1(1%)
D	12	30	0.4	7(16.7%)	25(83.3%)	3(1%)
E	12	43	1	12(27.9%)	31(72.1%)	5(%)
Total	50	193		48(25%)	147(76.2%)	9(12%)

Comment [SSL27]: How did you calculate the abundance and why is the total space empty?

195
 196 From the questionnaire shared to the 150 students, it was gathered that 30(20%) of the students treat
 197 malaria every 3months, 20(13.3%) every 6 months, 24 (16%) before resuming school, 76(50.7%)
 198 only when they fall ill to malaria.

Comment [SSL28]: Compare the different % responses for each parameter using chi-square and present it in form of a table

199 On the possession of LLINs, majority {81 (54%)} of the students have LLINs, while the remaining
 200 {69(46%)} students do not. Out of the 81 (54%) of the students that have the nets, 34 (54%) of them
 201 do not use it, 20(24.7%) use it every day, 8(9.9%) use it only when they remember, 4(4.9%) use it
 202 only when they are cold and 15(18.5%) of them use it anytime they like.

Comment [SSL29]: Please use chi-square to compare respondent responses for each parameter. Present this result in form of a scientific table.

203
 204 **DISCUSSION**

205 The results obtained in the study showed that the prevalence of malaria infection among Nnamdi
 206 Azikiwe university students living in Agbani-Ifite is high (90%). This result is in line with the
 207 findings of (11) conducted among first year students of the same university. This is relatively high
 208 when compared to 38.93% by (10) among students living in the same university hostel, 61% for
 209 students in University of Abuja by (12), and 59.4% recorded for post primary students of Umunede
 210 and Asaba by (13), though most of the study were carried out in the wet season. In contrast to our

211 finding, (14) recorded a low prevalence of 17% for students of University of Ibadan, Oyo State.
212 Major factor on the low prevalence is the awareness level of the disease by the students, knowledge
213 of the disease, prompt treatment upon infection and strict adherence to the control measures probably
214 brought about the low prevalence of malaria.

215 The high prevalence recorded in the study may be attributed to the fact that many of the students do
216 not have mosquito nets and among those that have, only (24.7%) of them use them judiciously
217 (everyday) despite being proved as an effective method of malaria intervention as adopted by the
218 Roll Back Malaria programme (15). A few, 4(4.9%), of the study population use the LLINs only
219 during cold weather conditions is in agreement with the findings of (16) that people do not use the
220 mosquito nets due to increased temperatures.

221 The results also showed a higher infection in males than females: out of 75 males, 68(90.7%) of
222 them were infected, and of the 75 females sampled, 67(89.3%) of them were infected although
223 there was no significant difference between prevalence of malaria between males and females. This
224 agrees with the findings of (17, 18) who reported that prevalence of malaria among the male gender
225 is higher than of the female. (19) also reported that the cause of higher prevalence observed in male
226 could be due to the fact that they expose their bodies more than females when the weather is hot and
227 thus increases their chances of being bitten by the mosquito. The sampled male students most often
228 exhibit a carefree attitude and pay little or no attention to damaged window nets, bad doors and the
229 use of mosquito nets compared to the female students.

230 The difference in malaria prevalence and number of *Anopheles* mosquitoes in the different locations
231 was significant ($P < 0.05$). This difference is mainly due to the differences in the availability of
232 breeding sites, use of ITNs and other personal protections from the bites of *Anopheles* mosquitoes
233 such as wearing clothes that properly cover the body, closing doors and ensuring the repair of
234 damaged doors, windows and torn nets. Locations C, D, E have many breeding sites for *Anopheles*
235 mosquitoes consisting of pools and puddles of various sizes majority of which were created
236 artificially. Poor drainage system and waste disposal was obvious especially at locations D and C
237 where water from various rooms collects through exposed gutters from the different rooms
238 channelled to the major collecting gutter; and majority of the students there do not use mosquito nets.
239 The use of interventions were highly practiced by the students in locations A and B especially from
240 location B coupled with the fact that sampled hostels from this location were mainly neat hostels
241 with clean surroundings. Good sanitation is maintained within the hostels.

242 Hence correlating *Anopheles* mosquito abundance with malaria prevalence, a positive correlation is
243 seen especially in Locations D and E. Positive correlation as it was seen in the study of (20) who
244 opined that since the *An. gambiae* species is a very effective vector of malaria, the presence of even
245 one is a big cause for public health concern; thus, the effect of forty-six of them in an area cannot be
246 over emphasized.

247 Also, the differences in mean *Anopheles* mosquito abundance in the various locations could be due to
248 the pattern of the room and the number of persons dwelling therein as observed during the course of

Comment [SSL30]: Compare this finding with that of Bamou R & Sevidzem SL. 2016. ABO/Rhesus blood group systems and malaria prevalence among students of the University of Dschang, Cameroon. Malaria World Journal, 7:4.

NB But take care because the study of Bamou and Sevidzem used rapid diagnostic kits and yours used microscopy.

Check tense

Comment [SSL31]: Please you did not use a correlation test so avoid using the term and rather use corresponded to.....

249 the study. In well built location (spacious, tiled, and having good window nettings and doors), fewer
250 number of mosquitoes were collected compared to houses with torn nets, loosely-fitted doors,
251 smaller space. Also larger numbers of mosquitoes were collected from rooms occupied by larger
252 number of persons (2-5 students) compared to rooms occupied by a single student. This is because
253 *Anopheles gambiae* sl are strongly attracted to the scent from the human body (21); therefore, the
254 more the people in a room the higher the concentration of the scent and a corresponding increase in
255 the number of mosquitoes attracted.

256 Despite the intervention, high malaria infection prevalence was still recorded and this could be
257 attributed to the night activities of the students such as parties, ranging from birthday parties to
258 departmental nights. The most common of these activities is night reading, normally practiced by
259 majority of the students and more often done in the open (Garba square) thereby exposing them to
260 infection from infected *Anopheles* mosquitoes.

261 Of the mosquitoes collected during larval sampling, 62% were *Anopheles* mosquitoes. More
262 collection was made in Location E with dirty water which has leaves as shades. The collection of
263 *Anopheles gambiae* sl in dirty water supports the finding of (22) that some species of *Anopheles*
264 *gambiae* mosquitoes can also breed in dirty water as against the general knowledge that *Anopheles*
265 mosquitoes breeds in a clean and clear water (23).The breeding sites with smelly dirty water
266 collected more *Culex* mosquitoes. Surprisingly, *Anopheles* mosquito larvae were collected in the
267 habitat with gasoline at location D, as it have also been reported in the study of (24). The outcome of
268 the sampling and the type of breeding habitat predominant in all the locations gives us an insight in
269 the abundance of the malaria vector

Comment [SSL32]: has

270 In conclusion, results from this study have shown how highly exposed the University students living
271 in the hostels are to malaria infection and a host of other mosquito borne diseases. Most of the
272 students though aware of the disease malaria and various preventive and therapeutic measures often
273 undermine the lethality of the disease and pay little attention to applying simple preventive measure
274 like the use of net by the students will go a long way in reducing the prevalence of malaria as the
275 practice will kill many endophagic and endophilic *Anopheles* mosquito and reduces the chance of the
276 vector living long enough to transmit malaria parasites.

Comment [SSL33]: Write conclusion clearly
