Exploration for Marble Deposit in Parts OF Okpella, South Southern Nigeria

4 ABSTRACT

3

The ultimate aim of the electrical resistivity survey is to determine the resistivity 5 distribution with depth on the basis of surface measurements of the apparent resistivity 6 7 and to interpret it in terms of geology. Marble deposit was investigated with the application of electrical resistivity method using Vertical Electrical Sounding (VES) 8 9 technique with the aim of characterising this deposit in parts of Okpella. Six (6) VES were 10 acquired using the Schlumberger array for data acquisition with current electrode 11 spacing varying from 1.0 to 150.0 m. The VES data obtained were interpreted using 12 ipi2win Software. The results showed three layers indicating subsurface geologic sequence probed 26.4 m and beyond with clay/clayey sand (23.3 – 219.1 Ω m), sand (423 -13 2040 Ω m) and marble (12661 - 404498 Ω m). The occurrence of marble deposit was 14 revealed at VES points at 1, 2 and 5 in the studied area. This study concluded that the 15 study area had occurrence of the marble deposits, which would be of economic 16 17 importance, if exploited.

21 **1. INTRODUCTION**

22 Marble, a crystalline, non-foliated metamorphosed limestone through the action of heat and pressure 23 occurs within the migmatite gneiss- schist-quartzite complex as relicts of sedimentary carbonate rocks. 24 These are Upper Proterozoic schist belt metasediments which are normally marked by a general absence 25 of carbonates. Such marble deposits appear to be limited to the western portions of the south and central 26 parts of the country [1]. The schist (metasediments) occurs as a supracrustal cover on the basement and 27 consists of quartz – biotite, calc-gneiss and marble, metaconglomerate and mica schist [2] - [7]. The 28 marbles are of varying colours of whitish, gravish, cream and pale greenish. The marble is predominantly composed of calcite with specks of iron sulphide and calc-silicate minerals. Marble is composed 29 30 essentially of calcite (CaCO3), dolomite [CaMg(CO3)2], or a combination of the two, with a fine- to 31 coarse-grained crystalline texture [8]. Marble is extremely valuable industrial rock raw material. 32 Construction (eg building, sculpture, monuments, and as dimension stones) and cement manufacturing 33 industries are principal consumers. It is also used in the production of chemicals, fertilizer, abrasives, 34 paint making, tooth paste, detergents, soaps, pharmaceuticals, cosmetics, chewing gum, sweets, water 35 treatment, soil treatment, ceramics making, asbestos making, industrial adhesives, paper conversion, livestock concentrate, chemical fillers (rubber and plastic products) and steel and iron refinery. 36

37 The high contrast in resistivity values between carbonate rock, clayey and sandy materials favours the 38 use of electrical resistivity method for determining the boundary between these Earth materials [9]. Since 39 the electrical resistivity of earth materials can be influenced by parameters such as rock matrix, porosity, 40 permeability, temperature, degree of fracturing, grain size, rock type and the extent of weathering. The electrical resistivity method is therefore adopted for this research. Proceeding to this research work, there 41 42 has been dearth of information on the existing literature of marble deposit in the area been investigated. Therefore the current effort is directed at unveiling the situation with a view to find an enduring solution in 43 44 characterising the marble deposit in parts of Okpella.

45

46 **1.1 LOCATION AND GEOLOGICAL SETTING**

The studied area lies within Latitudes 7.37563° and 7.35902° North and Longitudes 6.44548° and 47 48 6.44536° East (Figures 1a and 1b) of Okpella in the northern part of Edo State, Nigeria. Geologically, it 49 falls within the Basement Complex of south southern Nigeria which is underlain by undifferentiated older 50 Granite mainly coarse grained granite and porphyritic granite of the Pan-African older Granitoids. The 51 rocks are generally in the NW direction and dipping to the East. The Older Granites were first 52 distinguished from the "younger" alkaline granites by [10]. The schist belt of Okpella are seen to have 53 been severally invaded by the event of tectonic activities in the area giving rise to large mass of plutonic 54 and volcanic rocks which are of granitic origin. Relic folds are evident on the rock mass seen to be 55 floating as xenolithic structures with minor and micro folds which originated from the various stages of 56 metamorphism.

1.2 THEORETICAL BACKGROUND 62

63 The resistivity method provides a quantitative measure of the conducting properties of the 64 subsurface. In this method a series of potential differences are acquired at successively greater electrode 65 spacings while maintaining a fixed central reference point. The induced current passes through progressively deeper layers at greater electrode spacing. The potential difference measurements are 66 67 directly proportional to the changes in the deeper subsurface. Apparent resistivity values calculated from measured potential differences can be interpreted in terms of overburden thickness, water table depth, 68 69 and the depths and thicknesses of subsurface strata [10]. The two most common arrays used for VES are 70 the Wenner array and the Schlumberger array. Vertical electrical sounding (VES) field method that used 71 in this research involves the measurement of the variation of resistivity value with depth. This technique 72 can be used to find the depths of layers in the earth having anomalously high or low conductivities and to 73 determine the depth, approximate shape of ore bodies with anomalous resistivity. The foundation for 74 electrical resistivity theory is governed by Ohms law.

75	The resistance (R) of the wire to current flow can be expressed as:	
76	$R\alpha L/A$	(1)
77	$R = \frac{\rho L}{A}$	(2)
78	From Ohm's law,	
79	$R = \frac{\Delta V}{I}$	(3)
80	$\Delta V / I = \rho L / A$	(4)
81	$\rho = A\Delta V / IL$	(5)
82	Where	

- ρ is the resistivity (in Ohm-metre), L is the length of wire (in metres) 83
- A is the cross- sectional area of the wire (metre²), R is the resistance (Ohms) 84
- 85 I is the current (ampere).

86 2. MATERIALS AND METHOD

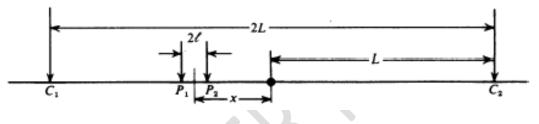

87 Geophysical surveys are efficient and cost-effective in providing geotechnical information since they

88 combine high speed and appreciable accuracy in providing subsurface information over large areas [12].

89 For this study, Vertical Electrical Sounding (VES) using Schlumberger array (Figure 2) was adopted in

90 order to study the variations in the resistivity distribution of the soil with depth. An electrical current is

91 passed through the ground and two potential electrodes allow us to record the resultant potential 92 difference between them, giving us a way to measure the electrical impedance of the subsurface 93 material. The distance between the potential electrodes is much smaller than the distance between the 94 potential and current electrodes. The most common configuration is to put the measuring dipole in the 95 centre of the array. The apparent resistivity is then a function of the measured impedance and the 96 geometry of the electrode array. The importance of electrical resistivity method makes its usefulness in 97 many fields like investigating natural resources, environmental problems, and engineering studies for the 98 last three to five decades. Six (6) VES were carried out which is enough for the anticipated depth of 99 investigation using Schlumberger configuration array with current electrode spacing varying from 1.00 to 150.00 m. The processing of the acquired data was done by plotting the apparent resistivity against half-100 current electrode spacing (AB/2) on a log-log graph sheets. The outcome of these served as input for 101 102 numerical iteration using ipi2win Software.

106 3. RESULTS AND DISCUSSION

Geoelectrical resistivity survey involving vertical electrical soundings have been used to characterise the 107 marble deposit in parts of Okpella. The summary of the interpreted results of the VES curves at each VES 108 109 stations are presented in (Table 1). Data generated from the Vertical Electrical Sounding using Schlumberger configuration was presented as geoelectric sounding curves. The results showed variable 110 composition of subsurface geologic sequence probed 26.4 m and beyond with clay/clayey sand (23.3 -111 112 219.1 Ω m), sand (423 - 2040 Ω m), marble (12661 - 404498 Ω m). This is accordingly represented in figure 113 3. The characteristic curve types obtained in the area are H and K curve types (Figure 4) depicting three 114 geoelectric layers. VES 1, 2 and 5 with resistivity values ranged from 12661 to 404498 Ωm shows the 115 existence marble.
