

## **Original Research Article**

### **GENDER INFLUENCE ON STUDENT'S PERCEPTION ABOUT MULTIPLE REPRESENTATIONS IN LEARNING CHEMISTRY AT NIGERIAN SECONDARY SCHOOL.**

#### **Abstract:**

This study aims at investigating the influence of gender difference in learning chemistry using multiple representation which was spurred towards obtaining an improved academic achievement. The study employed a descriptive research design using survey across the senatorial districts in Ondo state. Data collected were subjected to descriptive statistics while inferential analysis were carried out using Paired t-test Statistical Analysis. Findings from the study showed that there was no significant gender difference in the preferred effectiveness of multiple representation. However, female students showed more interest in the use of multiple representation in learning chemistry than the male students. Based on the research, teachers should permit better student interactions and engagements in their classroom for better understanding of chemistry context.

**Key words:** Multiple Representations, Chemistry, Learning, Gender Difference, Ondo State

## INTRODUCTION

Chemistry as a branch of science and a prerequisite subject for many science fields which contributes immensely to the technological growth of the nation. The study of chemistry entails the learning of concepts, established principles, laws and theories and also substantial activity-oriented laboratory work. Chemical representations refer to various types of formulas, structures, and symbols used to represent chemical processes and conceptual entities (e.g. molecules and atoms). Chemical representations can be viewed as metaphors, models, and theoretical constructs of chemists' interpretation of nature and reality (Hoffman & Laszlo, 1991).

The context of chemistry is different from other science subjects, which exists in three levels and are difficult to understand at the same time. The three levels being the macroscopic, microscopic and the symbolic representation levels (Johnstone, 2000). The macroscopic level chemical processes are observable, microscopic level of chemical phenomena are explained via the arrangement and motion of molecules, atoms, or subatomic particles. Chemistry at the symbolic level is represented by symbols, numbers, formulas, equations, and structures. The three levels are intertwined and there is need to understand how they are related. Except for experts in the subject, it is difficult to quickly move from one level to the other, therefore it should be done in stages for easy comprehension of the three levels. To help students understand chemistry at the three levels, earlier research have suggested a variety of teaching approaches, such as adapting strategies based on the conceptual change model (Lawrie *et al.*, 2009), integrating laboratory activities into class teaching (Johnstone, 2000), using concrete models (Copollo & Hounshell, 1995), and using technologies as learning tools (Kozma *et al.*, 2000) Among these approaches, the use of concrete models and technologies as learning tools seems to have high potential. Multiple linked representations provided by multimedia tools allow students to visualize the interactions among molecules and understand the related chemical concepts (Kozma *et al.*, 2000). Multiple representation of scientific concepts are provided for achieving good educational goals. Summarily, the advantage of multiple representation illustrated by a functional taxonomy falls into three broad classes proposed by Ainsworth (1999) are:

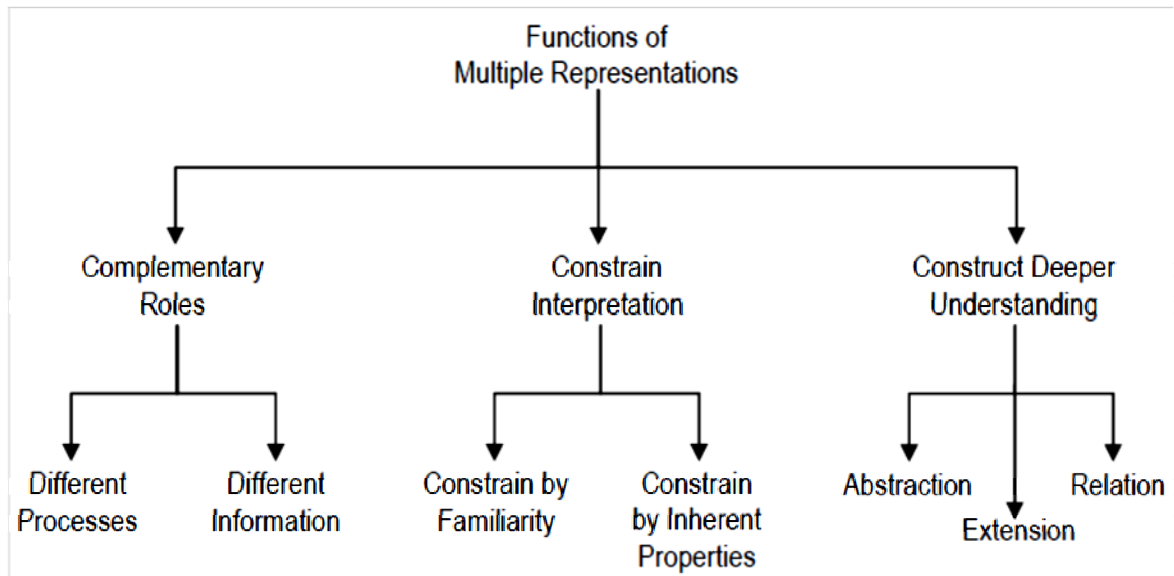

Figure 1: Functions of Multiple Representations (Anisworth 1999)

The constructivists recommend learning through active engagement and with understanding which is more permanent than memorisation of content or learning by equation or formula. It is argued that for deep learning to occur, students' need to be placed at the centre of the learning and supported to construct meaningful understanding out of experience and prior knowledge (Atherton, 2009; Driver *et al.*, 1994). Active engagement in activities provides opportunities for the students to receive, share and record information for processing.

Gender is a psychological term used in describing behaviours and attributes expected of individuals on the basis of being born as either male or female (Umoh, 2003). It is a cultural construct that differentiates roles, mental and emotional characteristics between females and males developed by a society. The studies of gender are not just mere identification of male and female sexes but have gone further to identify responsibilities assigned to opposite sexes and to analyze the conditions under which those responsibilities are assigned (Okeke, 2003). Gender is a major factor that influences career choice and subject interest of students.

In science education, differences in achievements and attitudes have been observed between boys and girls. Many researchers and educators proposed that gender difference is one of the factors that affect the teaching and learning of science. Gender differences in engagement and interest in many areas of science have been studied in the middle school in many countries (Bacharach *et al.*, 2003). It was found that gender differences may shape the student's perception of self-competence in various school subjects which may turn affect their achievements in

science. A variety of reasons have been presented to account for such gender differences in science education. It was found by Murphy (1997) that boys and girls are different in their interest and attitude from an early age. Additionally, Goman *et al.*, (1988) revealed that at age 15, more boys favour to read the accurate facts books while more girls like to read for understanding. Moreover, Kimbell *et al.*, (1991) showed that girls prefer to work and discuss with group while boys prefer to work independently. Furthermore, Morphy (1997) found that girls keep considering contextual features as a whole part of the science tasks while boys keep considering issues in isolation. Thus girls usually formulate more complex multivariable investigations that are difficult to work on. Din *et al.*, (2004) found that boy had high score in test with more earth and physical sciences item. Understanding of scientific knowledge but girls had higher score on recognizing question and identifying evidence items. It implied that boys clearly perform better understanding than girls particularly in the physical sciences. Bruce & Gabel (2002) observed that a more visual representation of chemical interaction has significant effect on both girls' immediate and delayed achievement for several representation of matter including traditional symbolic chemistry problems. Chang *et al.*, (2009) observed that boys showed higher learning interest in sustainability issues and scientific topics than girls. Evans *et al.*, (2002) found that girls' low interest in many areas of science was problematic because they are with low interest were more than those with high interest to have high science achievement scores. Furthermore, Catsambis (1995) found that boys were more likely to look forward to science class and think science would be useful to their future and were less afraid to ask questions in science classes than their girl peers.

### **Statement of Problem**

The important function of a school system is to improve the academic performance of students and produce a pool of skilled manpower irrespective of their gender. The Nigeria science education system over the years is faced with a lot of problems and one of the most serious problems is continuous poor performance of students in chemistry. This could be attributed to the way it is taught, students remain passive most of the time making chemistry learning dull, non-exciting and senseless information (Benjamin *et al.*, 2002). Furthermore, based on the local peculiarity of Nigerian culture in which gender-role differentiation is very much pronounced in our society. This places a very serious constraint on the academic performance of male and female students in chemistry thereby limiting the full participation, development and utilization

of individual potentials either directly or indirectly. Thus, the study is spurring to the improvement of chemistry teaching and learning at the senior secondary level.

### **Purpose of the Study**

The purpose of the study was to determine whether multiple representation has any significant effect on the learning of chemistry and the influence of gender on learning using multiple representation in Ondo State's secondary schools.

### **Research Questions**

The study was guided by the research questions:

- Does multiple representation has any significant effect on the learning of chemistry in Ondo State's secondary schools?

### **Research Hypothesis**

The null hypotheses was formulated to guide the study and tested at 0.05 level of significance:

- There will be no significant gender difference in effectiveness of multiple representation

## **METHODOLOGY**

The study employed a survey research design. The population of the study consists of all chemistry students in both public and private schools in Ondo State. A purposive sampling technique was used to constitute a sample of 600 (300 male and 300 female) senior secondary two (SS2) Chemistry students participated in this study across the three senatorial district of Ondo state. The choice of SS2 Chemistry students for the study was based on the fact that the students have had background knowledge and experience about Chemistry classroom to enable them to describe their situation.

### **Instrumentation**

The instrument used to collect relevant data for the study was Chemistry Learning Inventory (CLI). The Chemistry Learning Inventory (CLI) was a closed type questionnaire which allows for either strongly agree (SA), Agree (A), Strongly disagree (SD), or Disagree (D) responses from respondents. The instruments were validated by the researchers and other education experts.

### **Procedure for Administration of Questionnaire**

The researcher visited the participating schools for this study and administer the instruments to the students during the first term of 2017/2018 session. The study was conducted during normal

morning periods. Participants were requested to respond independently. Filled copies were retrieved on the spot to avoid instrument mortality. The instruments administered to the students were evaluated and data generated was collected for statistical analysis based on the research hypothesis.

### Data Analysis

The collected data in this study was analyzed using descriptive statistics of percentage, mean and standard deviation to answer the research questions. The hypotheses formulated were analysed inferentially using Analysis of variance (ANOVA) and Paired t-test statistical analysis to test the hypothesis at 0.05 level of significance.

### RESULT

The result on whether there is any significant gender effect of multiple representation on the teaching and learning of chemistry in Ondo State's secondary schools is shown in Table 1 below.

**Table 1: Mean And Standard Deviation of Respondent's Decision on the Gender Effect of Multiple Representation on Teaching and learning Chemistry in Ondo State's Secondary Schools**

S/N	ITEM	Mean		Standard Deviation	Decision
		M	F		
1	The use of different representation approach in Chemistry lessons such as graph, picture, model, concept map can aid proper understanding of Chemistry context and ideas	3.29	3.24	0.737	Agree
2	Adequate understanding of Chemistry ideas results in improved Students' performance during assessments and external examination	3.64	3.63	0.548	Agree
3	The type of representation strategy utilized by Chemistry teacher have influence on the Students' learning process	3.31	3.16	0.543	Agree
4	The context of Chemistry topic to be taught by the teacher should determine the representation approach to be used during teaching	3.31	3.27	0.572	Agree

The data on table 1 revealed that items had their mean above the cut-off of 2.50. This implies that most of the students used for the study agreed that there is gender effect of multiple representation on the teaching and learning of chemistry in Ondo State's secondary schools. The standard deviation on the ranges from 0.543-0.737. This revealed that the respondents were close to one another in their responses and that their responses are not too far from the mean. However, student's opinion based on gender across the three senatorial district about the significant of multiple representation on the teaching and learning of chemistry across the senatorial district are explicitly revealed in Table 2 below.

**Table 2: Percentage Analysis of Respondent's Opinion on the Gender Effect of Multiple Representation on Teaching and learning Chemistry in Ondo State's Secondary Schools**

OPTION	ONDO NORTH		ONDO CENTRAL		ONDO SOUTH		AVERAGE	
	Male	Female	Male	Female	Male	Female	Male	Female
Strongly Agree (%)	44.0	36.0	40.0	35.0	42.0	36.0	42.00	35.67
Agree (%)	51.0	61.0	52.0	58.0	49.0	58.0	50.67	59.00
Disagree (%)	5.0	3.0	8.0	5.0	9.0	6.0	7.33	4.67
Strongly Disagree (%)	-	-	-	2.0	-	-	-	0.66
Total (%)	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0

Table 2 above shows the percentage gender effect analysis of multiple representation on the teaching and learning of chemistry in secondary schools across the three senatorial district of Ondo State. The male analysis reveals that 95.0%, 92.0% and 91.0 while female analysis shows that 97.0%, 93.0% and 94.0% representing Ondo North, Ondo Central and Ondo South Senatorial district respectively have positive opinion that multiple representation have significant effect on teaching and learning of chemistry in secondary schools. On examination, 92.67% and 94.67% representing male and female respondent respondents hold on with the significant of multiple representation on the teaching and learning of chemistry in Ondo State's secondary schools. This suggest that female student tends to benefit more when utilizing multiple representation in teaching and learning of chemistry in Ondo State's secondary schools. Student's perception was considered based on their opinion about multiple representation and their interest. Hence, this shows that gender influence the student's choice of multiple representation in teaching and learning chemistry in Ondo State's secondary schools.

The hypothesis was tested by computing the response of the respondent on the effectiveness of multiple representation in teaching and learning of chemistry. The respondents were classified based on their gender into “Male” and “Female”. Thus, their response were compared for statistical significance using Paired t-test Analysis at 0.05 confidence level of significance. The computed results is described in Table 3.

**Table 3: Paired T-test Analysis on the Significant Gender Effect of Multiple Representation on the Learning of Chemistry in Ondo State’s Secondary Schools.**

**Paired Samples Test**

SEX	Mean	Std. Deviation	df	t <sub>cal</sub>	t <sub>crit</sub>	Sig.(2-tailed)
Male	3.39	0.596	599	1.887	1.960	0.060
Female	3.32	0.653				

Table 3 presents the Paired T-test analysis on the significant gender effect of multiple representation on the teaching and learning of Chemistry in Ondo state’s secondary schools. From the result of the paired sample T-test, the t-cal (1.887) is lesser than the t-crit (1.960). The null hypothesis (Ho) is thus retained and the Alternative Hypothesis (Ha) is rejected. Therefore, the Null Hypothesis (Ho) that there is no significant gender effect of multiple representation on the teaching and learning of Chemistry in Ondo state’s secondary schools is hereby retained. The result shows a mean response of male respondent (3.39) which is close to the female respondent (3.32) and their standard deviation (0.596-0. 653) reveals that their responses were close to one another. This is an evidence to deduce that there is no significant gender difference in student’s choice of multiple representation approach of learning chemistry. Student regardless of their gender tends to prefer learning using multiple representation method than the use of conventional methods.

## **DISCUSSION OF FINDINGS**

The students’ opinion about the use of multiple representations on the teaching and learning of chemistry based on their gender was examined.

The findings of the study proves that students preferred to be actively engaged with representational challenges including role-plays, concept maps, flow charts, 3D models, particulate and graphical representations in learning chemistry. Collaborations and shared ideas

in groups among the students makes learning more student-centered compared with the conventional method of learning obtainable in schools. Some literatures suggested that this type of classroom environment made the concept learnt easier to understand, real and accessible as the representations created during learning engages students in constructive and higher order thinking (Ainsworth, 1999; Carolan, *et al.*, 2008; Haslam *et al.*, 2009).

The teacher's role in the classroom is to facilitate students' learning not practicing an authoritarian approach that results in a traditional teaching style which disengages students from learning and students feeling that they are not supported during lessons (Tobin *et al.*, 1994). They further observed that when opportunity is provided for students to engage in learning tasks, it develops their problem solving skills and allows them to be more creative in life challenges.

The research have shown that gender has no significant influence on effectiveness of multiple representation on the learning of chemistry. This finding conforms to research by Igboegwu and Okonkwo (2012), who in their different studies found that gender does not significantly influence students' learning and achievement in chemistry.

Although, the effectiveness of the multiple representation among the gender showed that male students tends to be better in learning than female students. The finding agreed with Ekeh (2003) who found in their studies, at various times, that male students achieved better than the female students in science subjects (chemistry).

Hence, lively and learning-friendly chemistry classrooms gives learners the opportunities to express their understanding and interact among themselves and available resource materials. Student's perception of chemistry of been difficult, because of its abstract nature and fundamental chemical expression of formulas, equations and reactions will be flipped into an interesting subject of learning. This will remediate the persistent decline in academic achievement of chemistry students in public examination which have been a great concern to science educators, examination bodies and the general public.

## **CONCLUSIONS**

Within the limits of this study, it can be concluded that the use of multiple representation in teaching and learning of Chemistry have high potency of enhancing students' interest and academic performance in the subject. Furthermore, students are more interested to be actively engaged with representational challenges that included activities such as role-plays, models,

concept maps, particulate, graphical and flow chart representation of chemical reactions and participating in small group and whole class discussions. It will have a improve students' academic achievement and learning of Chemistry regardless of their gender. However, female students tend to show more passion towards the utilization of multiple representations in learning chemistry than the male students.
