1 Comparative Efficacy of Varied Concentrations imidacloprid in

2 the Laboratory Management of Termites (*Microtermes natalensis*)

3

4

ABSTRACT

Imidacloprid is termiticide that is slow acting timber and soil applied but can be 5 systematically transferred in the worker castes of termites. The main objective of this study is 6 to determine efficacy of imidacloprid in the control of termites on sand. Termiticides were 7 tested at Imidacloprid 200g/l concentrations (2ml/l, 4ml/l,6 ml/l and 8ml/l). Sand was used as 8 the only mode of application in the control of Microtermes natalensis. The experiment was 9 laid out in Randomized Block Design carried out on laboratory with five treatments and three 10 11 replicates. Data analysis was performed using special statistical software called STATA version 13. Pearson's Chi square test was performed to compare proportions between factors. 12 13 The results were reported in terms of tables and figures. However, termites attacked all untreated wood blocks regardless of wood species. It was concluded that Imidacloprid at 14 concentration of 6 Ml/L serves as the best concentration threshold required in the control of 15 termites on sand in the management of termites. It was recommended that soil is effective 16 mode of applying imidacloprid termiticide integratedly given that the right concentration 17 levels are utilized. 18

21 **1. INTRODUCTION**

Termites are an essential member of the soil ecosystem and are found throughout the world. 22 Their presence is particularly noticeable in tropical and subtropical regions where they 23 24 represent a significant portion (10%) of the animal biomass [1], when the estimate is refined 25 to include only soil insect biomass this value rises to 95%. The natural activities of termites help to improve soil pH, organic carbon content, water content and porosity [2]. By 26 improving and adjusting these soil parameters termites assist in creating conditions conducive 27 to primary production, in this process they cause considerable losses to crops, trees and 28 29 wooden work in buildings [3]. These termites are classified as serious pests which cost 30 millions of dollars in annual control [4]. Insecticide application is an effective strategy for termite control. 31

Soil termiticides are used to treat soil to establish a toxic zone against termite penetration [5]. Termites remain alive for days on imidacloprid-treated sand and if termites are removed from the treatment, are able to recover. [6] Reported that, this species are the one cause's serious damage to buildings, agricultural crops and trees.

36 2. MATERIALS AND METHODS

37 **2.1 Description of Study Site**

The research was carried out at the Forest Products Research Centre of the Kenya ForestryResearch Institute (KEFRI) located at Karura Forest, Nairobi.

40 2.2 Experimental Design

The experiment was carried out in Aug 2017. The experiment was laid out in a Randomised 41 42 Block design carried out in the laboratory with five treatments and three replicates. Testing was carried out using imidacloprid at the mass concentration of 200 g/l and fipronil 25 g/l 43 44 with the latter being the experimental standard. The Protocols for Assessment of Wood Preservatives; A production of the Australian Wood Preservation Committee (AWPC) (2007 45 revision) was used. The test species used were Eucalyptus grandis and Grevillea robusta. 46 The treatments using imidacloprid at 200 g/l mass concentrations were carried out at four 47 concentrations (2 ml/l, 4 ml/l, 6 ml/l and 8m/l) and fipronil 25 g/l mass concentration was 48 49 carried out at 10 ml/l concentrations.

50 2.3 Study Sample

51 The test chemical, imidacloprid 200 g/l was tested at four concentrations – 2 ml/l, 4 ml/l, 6 52 ml/l and 8ml/l. imidacloprid 200 g/l were tested against an approved and registered chemical 53 known as Fipronil 25 g/l that is used at concentrations of 10 ml/l. A total of 72 wood samples 54 were used in the study.

55 2.4 Laboratory Experimentation (Protocol)

The *E*.*grandis* and *G*. *robusta*, timber were sawn into cubes of about 1 cm^3 cubes. The cubes were labelled by giving each code number, weighed and recorded. The numbers of wooden 58 blocks were 72cubes. After that the cubes were subjected into a temperature of 161°Cin oven 59 for 24 hours. Then the weights were recorded. Sand were treated with imidacloprid 200 g/l with concentrations of 2ml/l, 4ml/l,6ml/l and 8 ml/l, Fipronil 25 g/l concentration of 10 ml/l 60 61 whereby the sand were treated with twenty millitres, at 3 cm radius. Untreated sand serves as control .Untreated wood blocks measuring 1cm³ were put onto the treated sand in each of the 62 bottles. Then subterranean termites of the species natalensis, from a single colony 63 comprising of 360 females and 40 males were introduced according to a procedure adapted 64 from AWPA E1-97 standard (Standard method laboratory for evaluation to determine 65 resistance to subterranean termites, 1997). The test bottles were then kept in an incubator at 66 temperatures between 25-28 °C for one month .Out of untreated wood blocks, the samples 67 68 that were exposed to termites were 3 at each concentration.

69 2.5Data Analysis

Descriptive statistics for measures of central tendency such as mean and standard deviation was used in summarizing continuous variables which assume normality distribution. Data analysis was performed using special statistical software called STATA version 13. Pearson's Chi square test was performed to compare proportions between factors. The results were reported in terms of tables and figures.

75 **3. Results**

In this research there was a total 72(100%) woods categorized into two equal numbers of wood species, each assuming 36(50%) proportion, All wood blocks were proportionally divided into six groups where 60 (83%) different woods species were tested on treated sand under five different levels of concentrations and the remaining 12(16.7%) different woods species tested under untreated sand were regarded as control group. All those woods were factored out into three identified replicates that is, S1, S2 and S3, whereby each replicate had captured a total of 24 (33.33%) wood blocks .

83 Table 1: Displays the distributions of various Characteristics studie

Characteristic studied		Sample (%)
Wood replicates	S1	24(33.33%)
	S2	24(33.33%)
	\$3	24(33.33%)
	Total	72(100%)
sand treatments	T1 or 2mls/lit	12(16.67%)
	T2	12(16.67%)
	Т3	12(16.67%)
	T4	12(16.67%)
	T5	12(16.67%)
	T6 or control group	12(16.67%)
	Total	72(100%)

84

85 Descriptive analysis presented the mean weight loss for wood blocks under treated sand as follows E.grandis 0.003(Std:0.02) and G. robusta 0.013(Std:0.04) while the mean weight 86 87 loss for untreated woods under untreated sand were as follows *E.grandis* was 0.1(std:0.06) 88 and G. robusta was 0.216(std:0.147). There was significant evidence to suggest that at least 89 one of the treatment concentrations which had been used to control termites from woods 90 block attack was different from the responsiveness of other treatment. From that it was noted 91 that at least one of untreated wood under treated sand had been slightly attacked by M. 92 natalensis termites, P-value=0.0308. But when the adjustment of replicates was applied then 93 the results changed to be insignificant, P-value=0.6325

95 Table 2: Summary statistics on weight loss of wood species exposed to *M. natalensis*

96 termites.

Wood species	Mean	Std	Sample	P-value
Treated E.grandis	0.003	0.02	30	0.0308
Treated G. robusta	0.013	0.04	30	
Control E.grandis	0.1	0.06	6	
Control G. robusta	0.216	0.147	6	

97

98 From the results above woodblocks treated with 2ml/l of imidacloprid were slightly attacked

99 but the one treated with 4ml/l and above were not attacked.

100

4. DISCUSSION

Despite recent advances in the treatment of woods against subterranean termites by using bait technologies more destroyed woods and greater deforestation was found to prevail, a problem which enforced the researcher in this study to exploit other methods of treatment application on woods. Furthermore, this research investigated on an appropriated concentration threshold to apply during control of termites. An effective concentration threshold was found to be 4 mills per liter (4 Ml/L) when imidacloprid was applied.

In this study it was found that sand were effective in controlling all termites species from destroying wood an information which contrasts the use of bait technologies as suggested in [7-8]. Finding in this study seems to support an earlier study which found that termite control largely depends on the use of soil termiticides for the prevention and treatment of structural infestations [9].

112

5. CONCLUSIONS

In laboratory test, imidacloprid at concentration rate of 2 Ml/L were ineffective in the controlof M. *natalensis*. There was insignificant difference in weight loss among timbers treated

with different concentration level of imidacloprid at the rate of 200g/l, although the *E.grandis* timbers treated with a concentration level of 2 mills per litre of water were destroyed by termites. Imidacloprid at concentration of 4 Ml/L serves as the best concentration threshold required in the control of M. *natalensis* termites treated sand in the laboratory management of termites. However, termites attacked all untreated wood blocks regardless of wood species. Soil were found to be the most effective mode of application in the control of M. *natalensis* termites.

122

134

6. RECOMMENDATION

123 In this research it was suggested that the best concentration threshold to be used to control 124 and even prevent any termites from destroying woods was 4 milliliters (4Ml/L) of 125 imidacloprid, That level of concentration was found to the cheapest and more effective, hence 126 stops termites from destroying woodblocks this can be achieved so long as recommended concentrations threshold would be applied. It was also discovered that 4 milliliters per litre 127 128 (4MI/L) were the best concentration threshold required to prevent and control M. natalensis, 129 on treated sand in the laboratory management of termites. 130 **COMPETING INTERESTS** 131 Authors have declared that no competing interests exist. 132 133
