

Enzymatic potentials of microorganisms associated with cassava retting

ABSTRACT

The enzymatic potentials of microorganisms isolated from retting cassava were evaluated for the purpose of pectinase, cellulase and amylase activities. Cassava tubers of 12 months old were collected from 3 different sources: Ahieke, Ndoru and Umuariga in Abia State. They were hand peeled, cut into cylinders, washed, submerged into water and allowed to ret. After retting a dilution of the retted tubers were inoculated into different media plates: De-Man Rogosa Sharp agar, Sabouraud Dextrose agar, Nutrient agar, Mannitol salt agar and MacConkey agar and incubated at 30⁰C for 3-5days. 35 isolates was identified in the retting cassava samples which are bacteria 25(71.43%) and fungi 10(28.57%). The bacterial isolates identified include *Bacillus subtilis*, *Escherichia coli*, *Staphylococcus aureus*, *Lactobacillus* spp and *Proteus* spp while fungi isolated were *Aspergillus niger*, *Rhodotorula* spp and *Saccharomyces cerevisiae*. The total viable counts of the isolates increased as the retting hours increased. *Lactobacillus* spp and *Saccharomyces cerevisiae* dominated the later stage of the fermentation. *Bacillus subtilis* has the highest percentage occurrence 8(22.9%) while *Rhodotorula* spp has the lowest percentage occurrence 2(5.7%). The production of amylase enzyme was recorded with all the isolates with the exception of *Staphylococcus aureus*. Production of cellulase and pectinase enzymes was selective among the isolates. Results from this study shows that enzymes like amylase, pectinase and cellulase from microorganisms played an important role in retting of cassava tubers.

Key words: Cassava tubers, enzymes, fermentation, microorganisms, retting

38 Cassava (*Manihot esculenta crantz*) is a potential shrub with an edible starchy root, which grows
39 in the tropical and sub-tropical areas of the world (Burell, 2003). It is one of the staple foods
40 consumed in Africa and other parts of the world. It was estimated that the crop provides about 40%
41 of all the calories consumed in Africa and ranks second only to cereal grains as the chief source of
42 energy in Nigerian diet (Umeh *et al.*, 2007). The tuber consist of 64-87% starch depending on the
43 stage of the growth or maturity of the tuber but very limited quantities of protein, fats, vitamins,
44 and minerals (Alloys and Mings, 2006). The roots contain considerable quantities of anti-nutrients
45 factors, cyanogenic glucoside. The cyanogenic potential of cassava is by far the single factor that
46 adversely constraints the use of cassava as food and feed for animals. This is as a result of the toxic
47 effect of cyanide on humans and animals that rely on cassava as food. Cassava has bitter and sweet
48 varieties. The presence of cyanogenic compounds which predominates in bitter varieties and
49 processes to reduce them were recently reviewed by (Montagnac *et al.*, 2009).

50 Different processing techniques are used to reduce cassava toxicity and selected antinutrients such
51 as, boiling, drying, steaming, baking, frying, soaking, fermentation, steam distillation, etc.
52 Fermentation is the common method of cassava processing and through it, cassava can be
53 processed into different food products such as *Fufu*, *garri*, *Lafun*, *chikwangue*, etc. Cassava retting
54 (fermentation) is a technique involving long soaking of cassava roots in water to affect the
55 breakdown of tissues. Retting is one of the simplest and lactic acid fermentation process for the
56 processing of cassava tubers into various African staple foods. It simply involves steeping of
57 cassava roots in water until they soften. However, this takes about three to four days under optimal
58 condition. In other conditions retting may take considerable longer for example, tubers older than
59 24months or during the colder seasons of the year. During the consequent fermentation, roots are

60 softened by the activities of microorganisms producing various enzyme, the endogenous
61 cyanogenic glycosides (linamarin and lotaustralin) are subsequently hydrolyzed to glucose and
62 cyanohydrins, which easily break down to ketone and hydrogen cyanide (HCN) (Achi and Akomas,
63 2006), and characteristic flavour developed through a pH decrease and organic acid production
64 (Ampe *et al.*, 1994). The fermentation process (retting) is characterized by the activities of certain
65 microorganisms which produces enzyme such as pectinases, amylase, etc resulting in the
66 breakdown of cassava tissues. The presence of unspecified microorganisms complicates the
67 control of the fermentation process and lead to the production of objectionable odours (Achi and
68 Akomas, 2006). This research work aimed at determining the enzymatic potentials of
69 microorganisms associated with cassava retting.

70

71 **2.0**

MATERIALS AND METHODS

72 **2.1 Sample Collection**

73 Cassava tubers of 12months old were collected from Umuariga, Ndoru and Ahiaeke Markets in
74 Umuahia, Abia State and taken to the laboratory for analyses.

75 **2.2 Sample processing and retting Procedure**

76 The cassava tubers were cleaned, hand peeled and cut into pieces. They were completely
77 submerged in 1000 ml Glass beaker containing tap water and allowed to ferment at ambient
78 temperature of $30\pm 2^{\circ}\text{C}$ until retting (softening) occurred. The extent of retting of the cassava tubers
79 was determined manually by feeling the degree of softness of the tubers with hand covered with a
80 sterile disposal hand-glove (Kobawilla *et al.*, 2005).

81

82 **2.3 Microbial Enumeration**

83 Ten grams of the retted cassava tubers samples were collected for microbial enumeration at
84 24hours intervals until retting was completed. The collected sample was homogenized using sterile
85 laboratory mortar aseptically and 1 g of the homogenized sample was serially in peptone water.
86 0.1 ml aliquot of suitable dilution was inoculated on De-Man Rogosa Sharp agar (MRS) for the
87 isolation of lactic acid bacteria; Sabouraud Dextrose Agar (SDA) for the isolation of fungi;
88 Nutrient agar for isolation and enumeration of heterotrophic bacteria; Mannitol Salt agar (MSA)
89 for the isolation of *Staphylococcus aureus*, and MacConkey agar for the isolation of coliforms
90 respectively in triplicates (Public Health England, 2014). The media plates for isolation of bacteria
91 were incubated at 35 °C for 48 hrs while the fungal culture plates were incubated at 22 °C for 5
92 days. After incubation, the plates were examined culturally and later sub-cultured to obtain pure
93 cultures. The pure cultures were stored in media slants.
94 The bacterial cultures were later Gram stained and subjected to biochemical and sugar
95 fermentation tests for identification.

96
97

98 **2.4 Identification of fungal isolates**

99 A drop of lactophenol cotton blue was placed on a clean glass slide. Using a sterile wire loop, a
100 small portion of the colony was cut from the culture and placed to the drop of lactophenol cotton
101 blue. The preparation was covered with a cover slip and pressed gently. It was gently heated to
102 remove air bubbles and to spread the fungus evenly throughout the preparation. It was then
103 examined under the microscope using x10 and x40 objectives (Kurtzman *et al.*, 2011).

104 **2.5 Determination of Activities of Microbial Enzymes during Cassava Retting**

105 The method of Adeyanju *et al*, (2007) was adopted. Overnight culture of each isolate was
106 harvested and introduced in 10ml freshly prepared nutrient broth and was incubated at 30 °C for 24
107 h. The broth was centrifuged at 150 rpm for 10min. The supernatant which contained the enzyme
108 was withdrawn and kept at 4 °C in a refrigerator for further analysis.

109

110 **2.6 Screening for enzyme production**

111 **2.6.1 Screening for production of Amylase enzyme**

112 Qualitative determination of amylase production was carried out using well cut assay with some
113 modifications. The agar plates were supplemented with 1% starch. After agar solidification, 10
114 mm diameter well was cut out aseptically using cork borer. The well was filled with the culture
115 filter (100µL) and incubated for 24 hrs at 50 °C. After incubation, the agar was overlaid with 1%
116 iodine solution and the hydrolytic zone around the well (clear zone) was measured. The negative
117 control was maintained by adding sterile water in a separate well (Ong *et al.*, 2011).

118 **2.6.2 Production of Cellulase enzyme**

119 The production of Cellulases enzyme using screening medium contains 1% (w/v) carboxymethyl
120 cellulose (CMC) by plate assay was performed using agar plate fortified with 1% (w/v)
121 Carboxymethyl cellulose (CMC). After solidification of Agar, the wells were cut aseptically by
122 cork borer puncher for 10mm diameter and the culture filtrate was poured to the well then the
123 plates and incubated for 24 hrs at 37 °C. To visualize the hydrolysis zone, the plates were flooded
124 with 0.1% Congo red solution and washed with 1 M NaCl. The formation of a clear zone of
125 hydrolysis indicated cellulose degradation. The ratio of the clear zone diameter to colony diameter

126 was measured in order to select for the highest cellulase producer. The largest ratio was assumed to
127 contain the highest activity (Khatiwada *et al.*, 201).

128 **2.6.3 Screening of Isolates for the Pectinase Activity**

129 The isolates were screened for pectinase activity using Pectinase screening agar medium (PSAM).
130 The medium was sterilized and poured in a petri dish and allowed to gel. After, wells were cut
131 aseptically by cork borer punch of 10mm diameter and the culture filtrate was poured then the
132 plate was incubated at 30°C for 24 hours to 2 weeks. At the end of the incubation period, the plates
133 were flooded with 50 mM Potassium iodide-iodine solution. A clear halo zone around the colonies
134 indicates the ability of an isolate to produce pectinase (Beg *et al.*, 2000).

RESULTS

141 Table 1 shows the bacterial isolates from retting cassava samples and they include *Bacillus subtilis*,
142 *Escherichia coli*, *Staphylococcus aureus*, *Lactobacillus* spp, and *Proteus* spp.

143 Table 2 shows the fungal isolates recovered from retting cassava tubers. They include two moulds:
144 *Aspergillus niger* and *Rhodotorula* spp and a yeast: *Saccharomyces cerevisiae*.

145 Table 3 shows the total viable count of isolates from retting cassava samples. The total
146 heterotrophic plate count was in the range: 1.94×10^6 cfu/ml - 2.52×10^6 cfu/ml while the total
147 coliform plate count was in the range: 2.014×10^6 cfu/ml - 7.47×10^5 cfu/ml. The total lactic acid
148 bacteria plate count was from 1.712×10^6 cfu/ml to 2.897×10^6 cfu/ml while the staphylococcal plate

149 count was in the range: 2.131×10^6 cfu/ml to 7.76×10^5 cfu/ml. The total fungal plate count was in the
 150 range: 1.823×10^6 cfu/ml to 2.808×10^6 cfu/ml.

151 Table 4 shows the succession of the microbial isolates during the cassava re All the bacterial and
 152 fungal isolates were found in the retting medium at the beginning of the fermentation. However, at
 153 the end of the fermentation, only *Lactobacillus* spp and *Saccharomyces cerevisiae* were recovered
 154 from the samples.

155 Table 5 shows the percentage occurrence of microbial isolates with a total of 25 bacterial and 10
 156 fungal isolates from the retting procedure. *B. subtilis* has the highest occurrence 8 (22.9%) while
 157 *Rhodotorula* spp had the lowest occurrence (5.7%).

158 Table 6 shows the enzymatic potential of isolates from retting cassava samples. All the isolates
 159 except *Staphylococcus aureus* exhibited amylase activity with diameter of clear zones ranging
 160 between 8.5 - 13.5 mm while cellulase activity was exhibited by all the isolates except
 161 *Staphylococcus aureus*, *Lactobacillus* spp and *Proteus* spp with cleared zones of 8.5 - 12.5mm.
 162 Only *Rhodotorula* spp, *Escherichia coli*, *Staphylococcus aureus* and *Proteus* spp did not exhibit
 163 pectinase activity. The diameter of cleared zones ranged from 8.0 - 13.0 mm.

220 **DISCUSSION**

221 The present research determined the enzymatic potentials of microbes associated with retting of
222 cassava. The predominant microbes in the fermenting medium were lactic acid bacteria which
223 contributed to the acidification of the medium and *Saccharomyces cerevisiae*. Oyedeji *et al.*, (2013)
224 reported that *Lactobacillus* spp was the dominant bacterium in the fermenting cassava for lafun
225 production by submerged fermentation. Sugars produced by fermenting medium were suitable
226 substrate for yeast that caused the number of yeast higher than molds. *Escherichia coli* detected at
227 the early stage was characteristics of acid fermentation. The increased acidity of the medium could
228 have resulted in the decreased growth of the species. Tetchi (2012) found that during solid state
229 fermentation of cassava in *attieke*, processing lactic acid bacteria became dominant and
230 contributed to the most acidification of the product. The progressive increase in the frequency of
231 lactic acid bacteria and fungi observed during the retting process (later stage of fermentation) may
232 probably be due to increased acidity which favoured the growth of the microorganisms, although

233 the pH of the retting medium was acidic at 24 h of incubation. The decrease in pH throughout the
234 fermentation period was due to the production of organic acids by associated microorganisms
235 during fermentation.

236 The cassava roots softness occurred as a result of enzymatic cell wall degradation of cassava tubers.
237 It was established that the cell wall degradation of the cassava tubers resulting to root softening is
238 attributed to the enzyme from both plants and the isolated microorganisms. Some of the isolates
239 were able to produce amylase, pectinase and cellulase enzyme. Kobawila *et al.*, (2005) reported
240 that *Bacillus subtilis* produced amylase enzyme that are necessary for the breakdown of starch to
241 sugar which are needed for the growth of other fermenting microorganisms. According to
242 Ogunnaike *et al.*, (2015), some yeast and fungi contributed to tissue cassava breakdown by
243 cellulase production. Enzymes from lactic acid bacteria hydrolysis cell wall components partially
244 such as hemicellulose, pectin that destroyed the firm structure of cell. Degradation of cellulose
245 leads to fragmentation and hydrolysis of cell wall and starch granules that facilitate starch granules
246 to leach (Adetunji *et al.*, 2016) and decreased starch content.

247 The presence of high pectinase production indicated the possibility of faster softening of cassava
248 roots. The ability of *Lactobacillus* spp to produce a high degree of zone of inhibition of pectinase
249 enzyme suggests that it is of great important in retting period which therefore will aid in faster
250 retting of cassava roots.

251 Amylolytic activities of microbial strains in cassava contributes to the breakdown of cassava starch
252 to simple sugar thereby increasing the energy density cassava and providing carbon source for
253 lactic acid bacteria in view of the fact that amylase is a rare trait among lactic acid bacteria isolated
254 from starchy foods (Ogunremi and Danni 2011). Lactic acid bacteria are most responsible for

255 acidification during cassava retting (Bouatemin *et al.*, 2012). It was recorded that among all the
256 isolates it was only *Staphylococcus aureus* that could not produce any of the assayed enzyme. The
257 occurrence of *Staphylococcus aureus* and *Enterobacteriaceae* may be as a result of contamination
258 from cassava sample source or water, containers, and utensils used in preparation of the
259 soaking/retting of cassava roots.

260 CONCLUSION

261 Among all the enzymes assayed, only amylase was produced by all the isolates except
262 *Staphylococcus aureus*. This shows that amylase played an important role in retting of cassava
263 tubers (fermentation).

264 5.3 RECOMMENDATIONS

265 Results from this study have shown that enzymes produced by microorganisms involved in cassava
266 fermentation are the major factors affecting cassava retting. Therefore, further studies should focus
267 on the development of techniques in high production of enzymes for utilization in the cassava
268 based food industries.
