

# DEVELOPMENT OF RAINFALL INTENSITY - DURATION – FREQUENCY MODELS FOR AKURE, SOUTH-WEST, NIGERIA

## ABSTRACT

The rainfall Intensity-Duration-Frequency (IDF) relationship is widely used for adequate estimation of rainfall intensity over a particular catchment. A 25 year daily rainfall data were collected from Nigerian Meteorological Agency (NIMET) Abuja for Akure station. Twenty five year annual maximum rainfall amounts with durations of 5, 10, 15, 20, 30, 45, 60, 90, 120, 180, 240, 300 and 420 minutes were extracted and subjected to frequency analysis using the excel solver software wizard. A total of six (6) return period specific and one (1) general IDF models were developed for return periods of 2, 5, 10, 25, 50 and 100 years using Gumbel Extreme Value Type I and Log Pearson Type III distributions. Anderson Darling goodness of fit test was used to ascertain the best fit probability distribution. The  $R^2$  values range from 0.982 to 0.985 for GEVT I and 0.978 to 0.989 for Log Pearson type III while the Mean Squared Error from 33.56 to 156.50 for GEVT I and 43.01 to 150.63 Log Pearson Type III distributions respectively. The probability distribution models are recommended for the prediction of rainfall intensities for Akure metropolis.

Keywords: IDF models, log Pearson Type III distributions, Excel Solver, goodness of fit test, Akure.

## 1. INTRODUCTION

The Rainfall Intensity Duration Frequency (IDF) relationship is one of the most commonly used tools for the design of hydraulic and water resources engineering control structures. The IDF relationship is a mathematical relationship between the rainfall intensity, duration and the frequency (return period). The establishment of such relationship was done as early as 1932 (Bernard, 1932). The knowledge of frequency of extreme events like floods, high winds droughts and rainstorm helps in planning and design for these extreme events (Hosking and Wallis, 1997). The planning and designing of various water resources projects requires the use of rainfall intensity-duration-frequency (IDF) relationship (El-sayed, 2011). This relationship is determined through frequency analysis of data from meteorological stations. The IDF formulae are the empirical equations representing a relationship among maximum rainfall intensity (as dependent variable) and other parameters of interest such as rainfall duration and frequency (as independent variables). There are several commonly used functions found in the literature of hydrology applications (Chow et al., 1988). Owing to its wide applications, accurate estimation of intensity-duration-frequency relationship has received attention from researchers and scientists from all over the world (Mohammad Zakwan, 2016). All functions have been widely applied in hydrology. The IDF relation is mathematically stated as follows:

$$I = f(T,d) \tag{1}$$

Where T is the return period (years) and d duration (minutes). Examples of three different types of empirical equations was documented by Nwaogazie & Masi (2019); Itolima & Nwaogazie (2017).

39 **2. MATERIALS AND METHODS**

40 **2.1 Description of Area of Study**

41 Akure is in Ondo State which is one of the States in Nigeria created on February 3, 1976 from the  
 42 former Western State. It lies within 7<sup>0</sup> 10' N and 5<sup>0</sup> 05' E. Akure is located in the rain forest of  
 43 Nigeria. The available rainfall data (amount and duration) obtained from NIMET covered the period  
 44 between 1986 and 2010.

45  
 46 Figure 1: Location Map of Akure in South-Western Nigeria (Map data © 2019 Google)

47 Precipitation is characterized by a double maxima rainfall which starts from April and ends in  
 48 October, reaching its peak in June and September. The average annual rainfall is about 1,422mm with  
 49 some variations within the metropolis (analysed NIMET data).

50 **2.2 Data Collection & Analysis**

51 The major material used for this work is rainfall data comprising of rainfall amount and duration. The  
 52 twenty five (25) year rainfall data included data ranging from 1986 to 2010. The data were obtained  
 53 from Nigeria Meteorological Centre (NIMET) office Abuja, Nigeria. The data arrangement involved  
 54 sorting the mean data according to years, rainfall intensities and durations. The rainfall intensities  
 55 selected were the maximum values for each year for all the years analysed.

56 The annual maximum rainfall amount was obtained by selecting the maximum amount of rainfall for  
 57 each year for 5, 10, 15, 20, 30, 45, 60, 90, 120, 180, 240, 300, and 420 (duration - minutes) for the 25  
 58 years. Table 1 shows the ranked observed annual maximum rainfall amounts for Akure.

59 Table 1: Ranked Observed Annual Rainfall Amounts for Different Durations for Akure

Annual Maximum Rainfall Amount (mm)													
Rank	Duration of rainfall (minutes)												
	5	10	15	20	30	45	60	90	120	180	240	300	420

60 The rainfall amounts in Table 1 were converted to intensity (mm/hr) by dividing the amount of rainfall  
61 by the duration then multiplying by 60. For instance given an amount of 70.3mm and duration of 15  
62 minutes yields 281.3 mm/hr. Table 2 shows all the intensities for various durations.

63 Table 2: Ranked Observed Annual Rainfall Intensities (mm/hr) for different Durations (mins) for  
64 Akure

Year	Convert to intensity (mm/hr)

65 The magnitude of rainfall intensities were obtained using frequency analysis. Log Pearson Type III  
66 distribution was used to obtain the magnitude of rainfall intensities for different return periods.

67

### 68 2.3 Gumbel's Extreme Value Type I (GEVT- 1) Distribution

69 Gumbel distribution is one commonly used probability distribution for obtaining the rainfall  
70 intensity values. The rainfall intensity values were obtained using Equation (2) (Nwaogazie & Masi,  
71 2019)

$$72 X_T = \bar{X} + K_T S \quad (5)$$

73 Where  $X_T$  = rainfall intensity values (magnitude of hydrologic event)

74  $\bar{X}$  = mean;  $K_T$  = Gumbel's frequency factor; S = standard deviation

75 The Gumbel's frequency factor is obtained using Equation (3).

$$76 K_T = -\frac{\sqrt{6}}{\pi} \left\{ 0.5772 + \ln \left[ \ln \left( \frac{T}{T-1} \right) \right] \right\} \quad (6)$$

77 Where T = return period (years)

78 For example, Gumbel frequency factor for a 5 years return period

$$79 K_T = -\frac{\sqrt{6}}{\pi} \left\{ 0.5772 + \ln \left[ \ln \left( \frac{5}{5-1} \right) \right] \right\} = 0.719$$

80 The resulting Gumbel  $K_T$  values for different return periods as calculated are shown in Table 3.

81

82 Table 3: Gumbel frequency factor for Akure IDF modeling

Return Period	2	5	10	25	50	100
$K_T$ values	-0.16425	0.719	1.304	2.044	2.592	3.1363

83

84 **2.4 Log Pearson Type III (LPT III) Distribution**

85 Log Pearson type III distribution is one commonly used probability distribution for obtaining the  
86 rainfall intensity values. The rainfall intensity values were obtained using Equation (5)

87 
$$\text{Log } X_T = \text{Log } \bar{X} + K_T \text{Log } S \quad (7)$$

88 Where  $X_T$  = rainfall intensity values (magnitude of hydrologic event)

89  $\bar{X}$  = mean;  $K_T$  = Log Pearson frequency factor;  $S$  = standard deviation

90

91 Log-Pearson frequency factor can be obtained from the frequency table given in standard  
92 textbook using the return period and the skewness from Table 3 as follows:

93 For example, Log-Pearson distribution frequency factor for a 10 mins duration and 5 years return  
94 period with coefficient of skewness = 0.366734 was calculated to be 0.81866.

95 Table 4 gives the computed summary of  $K_T$  values for Log-Pearson distribution for various durations  
96 and different return periods computed.

97 Table 4: Log-Pearson frequency factors for various durations and return periods

Frequency Factor $K_T$

98

99 **Calibration of Sherman (1932) IDF model**

100 Sherman's modified IDF model is given as (Chow et al, 1988)

101 
$$I = \frac{cT_r^m}{T_d^a} \quad (6)$$

102 Equation (6) is non-linear power law that was calibrated for c, m, a parameters using intensity,  
103 duration and return period values in Table 1 and Excel Optimization Solver (Nwaogazie & Masi,  
104 2019).

105 **2.5 Goodness of fit test**

106 The result in Table 1 was subjected to Anderson-Darling test to ascertain the probability distribution  
107 that best fit the rainfall annual maximum amount. This is a nonparametric test of the equality of  
108 continuous, one dimensional probability distributions that can be used to compare a sample with a  
109 reference probability distribution. Gumbel Extreme Value Type I (GEVT-1) and Log-Pearson Type 3  
110 (LPT-3) best fit the rainfall intensities with significant values of 0.7570 and 0.7538 at 5% confidence  
111 level respectively.

112 **3. RESULTS**

113 **3.1 Development of Intensity Duration Frequency (IDF) Models**

114 Figure 2 represents the rainfall intensity values for various durations for the different return periods  
115 using Gumbel Extreme Value Type I distribution.

116

117

118 Figure 2: Intensity Duration Curve (IDF) curves for Gumbel Extreme Type 1 distribution plotting  
119 Intensities (mm/hr) against durations (mins) for Akure

120  
 121 The intensity duration frequency models were calibrated using the Microsoft Excel Solver. The  
 122 method adopted uses the least square criteria to obtain the model parameters. Table 4 gives a  
 123 distribution of developed IDF models for Gumbel Extreme Value Type 1 distribution.

124 Table 5 gives a distribution of developed IDF models for Gumbel Extreme Value Type 1 distribution.

125  
 126 Table 5: Developed IDF Models for different return periods using Gumbel Extreme Value Type 1  
 127 distribution rainfall intensities values for Akure.  
 128

Return Period	IDF Model $\pm$	Coefficient of Determination ( $R^2$ )	Mean Squared Error (MSE)
2	$I = \frac{4.766T_r^{6.428}}{T_d^{0.512}}$	0.985	33.56
5	$I = \frac{2.181T_r^{3.426}}{T_d^{0.519}}$	0.985	60.27
10	$I = \frac{1.646T_r^{2.582}}{T_d^{0.522}}$	0.984	84.55
25	$I = \frac{1.291T_r^{1.972}}{T_d^{0.525}}$	0.983	122.738
50	$I = \frac{1.170T_r^{1.675}}{T_d^{0.527}}$	0.982	156.496
100	$I = \frac{1.098T_r^{1.457}}{T_d^{0.528}}$	0.982	194.51

129  $\pm$  return period specific IDF models

130 The general IDF models was developed using Excel Spread Sheet Solver tool. The least  
 131 squares equations were programmed accordingly.

132 
$$I = \frac{407.886T_r^{0.175}}{T_d^{0.525}} \quad (7)$$

133 We note the following results: coefficient of determinant ( $R^2$ ) = 0.982; Mean Squared Error = 125.70

134 mm/hr

135

### 136 3.2 Development of Intensity Duration Frequency (IDF) Models

137 Figure 3 shows the rainfall intensity values for various durations for the different return periods using  
 138 Log Pearson Type III distribution.

140

141 Figure 3: Intensity Duration Frequency (IDF) curves for Log Pearson Type III distribution for Akure.

142 The intensity duration frequency models were developed using the Microsoft Excel Solver. The  
 143 method employs the least square criteria to obtain the model parameters.

144 Table 6 gives a distribution of developed IDF models for Log Pearson Type III distribution for Akure

145

146 Table 6: Developed IDF Models for different return periods using Log Pearson Type III distribution  
 147 rainfall intensities values for Akure.

148

Return Period	IDF Model	Coefficient of Determination (R <sup>2</sup> )	Mean Squared Error (MSE)
2	$I = \frac{4.74T_r^{6.366}}{T_d^{0.500}}$	0.980	43.01
5	$I = \frac{2.167T_r^{3.400}}{T_d^{0.505}}$	0.978	83.48
10	$I = \frac{1.642T_r^{2.576}}{T_d^{0.516}}$	0.980	105.23
25	$I = \frac{1.295T_r^{1.986}}{T_d^{0.534}}$	0.984	125.12
50	$I = \frac{1.185T_r^{1.698}}{T_d^{0.550}}$	0.987	136.96
100	$I = \frac{1.105T_r^{1.493}}{T_d^{0.568}}$	0.989	150.63

149

150 A general IDF model was also developed. This model enables one to predict the intensity of rainfall of  
151 any duration and any return period.

152

153 
$$I = \frac{402.607 T_r^{0.201}}{T_d^{0.540}} \quad (8)$$

154 We note the following results: coefficient of determinant ( $R^2$ ) = 0.984; and Mean Squared Error =  
155 127.47

156 Excel Solver Log Pearson Type III model parameters trial solution for 5 year return  
157 period specific IDF model has eleven (11) iterations before convergence (see Table 7).

158 Table 7: Excel Solver iteration distribution to convergence

S/NO	c	M	a
1	1	1	1
2	1.458558	1.738022	0
3	1.754711	2.433231	0
4	1.752072	2.426307	0.06467
5	2.033457	3.163496	0.32475
6	2.116698	3.355978	0.42475
7	2.145857	3.352741	0.479676
8	2.165626	3.398482	0.502807
9	2.167149	3.40017	0.505001
10	2.167155	3.400187	0.505003
11	2.167155	3.400187	0.505003

179

180 **3.2 Comparison of Observed and Predicted Rainfall Intensity**

181 The intensity duration frequency curves were obtained by plotting the predicted rainfall  
182 intensity values against corresponding durations for different return periods. The IDF  
183 curves for Akure are as shown in Figures 4 - 6.

184

185

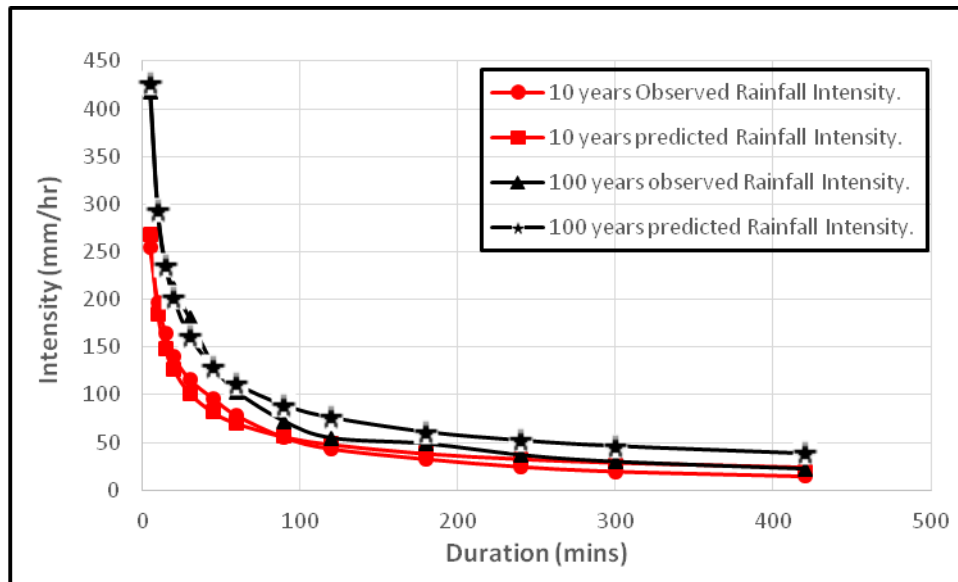

186 Figure 4: Observed rainfall intensity compared with predicted for 2 and 10 year return period for Log-  
 187 Pearson Type-3 distribution

188

189

190 Figure 5: Observed rainfall intensity compared with predicted for 5 and 25 year return period for Log-  
 191 Pearson Type-3 distribution for Akure

192

193 Figure 6: Observed rainfall intensity compared with predicted for 10 and 100 year return period for  
 194 Log-Pearson Type-3 distribution for Akure

195 **3.3 Comparison of Regression Approach and Excel Optimization Solver results for model parameters,**  
 196  **$R^2$  and MSE**

197

198 Table 8 (an extension of Table 5) clearly shows the result from Excel Optimization Solver option is  
 199 superior to the normal regression method, the conventional simultaneous solution using matrix i.e.  
 200 Gauss elimination, inverse or determinant approach (Nwaogazie & Masi, 2019).

201

202 Table 8: Results from regression approach and excel solver optimization approach (Log Pearson Type  
 203 III, 2 year return period)

204

Method	C	m	A	$R^2$	MSE
Regression	65.52	3.544	0.675	0.885	324.40
Excel Solver	4.74	6.366	0.500	0.980	43.01

205

206 **4. CONCLUSION**

207 The developed model for Log Pearson Type III is in agreement with literature theory  
 208 which shows higher intensity occurring at lower duration and lower intensity at higher  
 209 duration. The prediction of rainfall intensity with the PDFs showed a good match with  
 210 observed intensity values. The log Pearson Type III model ranked as the best with  
 211 respect to MSE 43.01 and  $R^2$  0.989 in the return period specific model when compared  
 212 with GEVT-I with MSE 33.56 and  $R^2$  0.985. The comparison of PDF and non-PDFs  
 213 shows that the former has lesser MSE value than the later; 43.01 and 324.40  
 214 respectively.
