# Energy efficiency “Example of Adana Yüreğir wastewater treatment plant”

## Energy efficiencies Assessment Adana Yüreğir wastewater treatment plant- Turkey

Comment [I1]: Please consider this theme

### ABSTRACT

**Abstract:** The purpose of this study is to analyze the design and operating parameters of influent and effluent for Yuregir Wastewater Treatment Plant (WWTP) of Adana Metropolitan Municipality and to make a comparison of the economic analysis system. The data of Yuregir WWTP regarding the amount of treated wastewater ( $m^3/month$ ), the amount of produced gas ( $m^3/month$ ), the energy withdrawn from the grid (kWh/month), and the electricity generated from the generator (kWh/month) were obtained for the year 2017. In the light of this information, the relations of the amount of treated wastewater and energy, the amount of produced gas and energy, and the energy generated and drawn from the grid were examined. It was observed that the average amount of wastewater treated and produced gas at the facility were  $2\,517\,831\ m^3/month$  and  $134\,596\ m^3/month$  while the generation of electricity from the generator and energy recovery as energy efficiency were  $317\,166\ kWh/month$  and  $49,72\%$ , respectively. Based upon the calculations made, it was observed that the energy consumption unit was reduced when the organic loading removal was increased at the WWTP.

Comment [I2]: Very short and inconclusive abstract, please make it conclusive by adding some more material , like recommended options for optimum gains  
2. Also mention mention environmental issues arose during heat generation from biomass and how these were tackled

The amount of wastewater resulting from the population growth and rapid industrialization is increasing day by day, and the necessity of disposing of off such wastes without harming the environment is and has become a legal , social and environment up-keeping obligation. arises. The waste sludge retained remaining after the treatment, called as biowaste, should be disposed of in a safe manner [1]. Such wastes are usually removed and evaluated using a variety of methods. These are sanitary landfill, incineration, composting, and deep sea discharge system [2]. In the same way, wastewater treatment for developing countries is located at the beginning of the question, which is still full of unsolved. The main reason for this is the high investment and operating costs [3,4]. Depending on the energy needs with rapid urbanization and technological developments, the environment of water, soil, and air

30 are excessively polluted such as mining operations, fertilizers and agricultural medicines  
31 used in agriculture [5,6]. Wastewater treatment plants in order to reduce wastewater damage  
32 to the environment and to ensure the continuity of the available water are becoming  
33 increasingly common. Today, a large number of systems available are applied to wastewater  
34 treatment. Activated sludge systems, stabilization ponds, trickling filters and biological  
35 systems such as anaerobic treatment are widely used for domestic wastewater treatment. Of  
36 these technologies, anaerobic digestion, which is a biological decomposition of organic  
37 matter in the absence of molecular oxygen, can be examined as one of the standard  
38 technologies for wastewater and stabilizing wastes. The products of anaerobic digestion are  
39 gases principally composed of methane (CH<sub>4</sub>) and carbon dioxide (CO<sub>2</sub>) and the stabilized  
40 biosolids. Anaerobic degradation may either occur in nature spontaneously or in a controlled  
41 environment such as a biogas system. Depending on the waste stream and the system design,  
42 biogas is used as an energy source and typically consists of 55 to 80% methane; the  
43 remaining composition is primarily carbon dioxide, trace gases such as hydrogen sulfide,  
44 nitrogen and water. On the other hand, stabilization ponds within developing, tropical, or  
45 subtropical climate areas are mostly preferred for domestic wastewater treatment plant [7].  
46 The cost components and operational requirements for wastewater treatment plants are  
47 important in developed countries. Therefore, these parameters as the decision-makers play  
48 a role for the selection of treatment plant type [8].

**Comment [I3]:** Biogas is generally composed of approximately 55 to 65 percent methane and 30 to 40 percent carbon dioxide. Other components include nitrogen, hydrogen, hydrogen sulfide, and various other impurities

49 **1.1 The Features of Treatment Efficiency, Energy, Operation and Maintenance, and**  
50 **Flowrate of Wastewater Systems:** The most important information needed for the process  
51 selection is collected under this title.

52 **1.2 Treatment Level:** The treatment level is determined to analyze the main wastewater  
53 parameters such as pH, Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand  
54 (COD), Suspended Solids (SS), Nitrogen, Phosphorus, etc. When selecting a treatment  
55 process, the discharge limits of wastewater into the receiving environment should be  
56 considered after identifying the treatment removal efficiencies .

57 **1.3 Fluctuation and Reliability in Treatment Efficiency:** Wastewater flow and pollution  
58 characteristics show a continuous fluctuation. Therefore, the discharge standard should be  
59 supplied in statistical basis.

60 **1.4 Other Process Requirements:** Required fields needs, energy issues (minimum energy  
61 use and energy shortages), easy and cost-effective availability of equipment, the trained  
62 personnel requirement, maintenance problems (machinery, equipment, etc.), sludge  
63 production and disposal (sludge treatment creates a significant part of the total treatment  
64 cost), existing hydraulic load, hydraulic head loss in the plant, treatment method, design  
65 criteria, and other related needs.

66 **1.5 Energy Saving:** Energy conservation and energy saving in order to design the  
67 wastewater treatment plant should be given significant importance. A two-step approach can  
68 be applied on energy issue. The first approach, it can be done to save energy and to choose  
69 the applicable methods without increasing the cost and complexity of the treatment plant.  
70 Therefore, it should be the property of moderation in technology, process and equipment  
71 should carefully be selected, and it should be gone to useful engineering and architectural  
72 design. The second approach is to concentrate on more than just the cost analysis  
73 processes, which are more advanced equipment and devices. The feasibility of this latter  
74 approach is limited only by the developed countries. Conventional energy sources with  
75 possible wind and solar energy applications can be supported. Use of facilities for this type  
76 of alternative energy sources should be investigated for the operation of the pumps in  
77 sewage systems, ventilation motors and other equipment. Advanced devices can be used in

78 recovering the waste heat energy. Among them, methane recovery to produce heat and  
79 power from the sludge digesters is extremely important [9].

80 **2.0 Literature Review**

81 **3.0 Study Objectives**

82 **4.0 Methods and Materials**

83 **2. DETERMINATION OF ENERGY CONSUMPTION**

84 **4.1 Determination of Energy Consumption.**

85 The total amount of energy consumed in the plant was calculated by the sum of values of  
86 the transformer taken every day. Energy calculations were carried out by measuring the  
87 amount of the generator produced and withdrawn from the grid in the plant. Daily input and  
88 output flow values, total energy consumption, and the design parameters for the physical  
89 treatment units, biological treatment units, other units and the whole plant were obtained for  
90 Yuregir Wastewater Treatment Plant (WWTP) of Adana Metropolitan Municipality. By means  
91 of these data obtained, input pollution load and the removal efficiencies of the plant, energy  
92 value withdrawn from the grid, electricity generation of the generator, and their relationships  
93 were successfully examined. Likewise, the removal energy values in terms of kWh/m<sup>3</sup> for the  
94 total energy consumption and the amount of energy consumed per person were calculated.  
95 Monthly sewage sludge and energy values of Yuregir Wastewater Treatment Plant for the  
96 year 2017 were presented in Table 1 and Table 2.

97 **Table 1. Yuregir wastewater treatment plant 2017 monthly sewage sludge values**

127

128 In this study, the energy consumption and production analysis in one of the wastewater  
 129 treatment facilities of Adana were performed. For this purpose, the amount of energy  
 130 consumed in the monthly time period for the year 2017 during under the titles of the physical  
 131 treatment, biological treatment, and others was determined for the separate units and the  
 132 whole plant. Findings belonging to the plant are presented in Table 1, Table 2, Figure 1, 2, 3,  
 133 and 4. The following conclusions are reached upon analyzing the obtained data from these  
 134 tables and figures.

135 **5.1.1** As can be seen from Figure 1, 2, 3, and 4; when the pollution load of input and output  
 136 increases, the unit energy consumption is reduced as expected (although the total  
 137 energy consumption increases). The increase in the pollution load reduces the unit  
 138 energy consumption although the energy consumption of the plant is same. Moreover,  
 139 as it can be seen again from the same tables, the consumption of operational energy  
 140 for the plant is linear with the pollution load of input.

141 **5.1.2** When examining the energy consumption of the plant, the average monthly energy  
 142 consumption of 637 846 kWh is determined for the whole plant.

143 **5.1.3** If the average monthly flow rate and energy consumption values of the plant are  
 144 discussed, the amount of energy consumption per cubic meter flow for the whole plant

145 is included. These values are found to be 2 517 831 m<sup>3</sup>/month (average flowrate), and  
146 0,253 kWh/m<sup>3</sup> (the total for the whole plant), respectively.

147 5.1.4 If the equivalent population found in design calculations and input flow coming to the  
148 plant are discussed, the amount of water consumed per person per month is included.  
149 This value for the year 2017 can be calculated as follows:

150 = (Average flow rate) / (Equivalent population)

151 = 2 517 831 (m<sup>3</sup>/month) / 588832 (person)

152 = 4,2759 m<sup>3</sup>/month/person

153 = 4276 L/month/person

154 5.1.5 If the average monthly energy consumption of the whole plant and the equivalent  
155 population found in design calculations are discussed, the amount of energy  
156 consumed per person can be found. This value for the year 2017 can be calculated  
157 as follows:

158 = (Average monthly energy consumption) / (Equivalent population)

159 = 637846 (kWh/month) / 588832 (person)

160 = 1,083 kWh/person

161 = 1083 W/person

## 162 5.2 Challenges

# 163 4. CONCLUSIONS AND RECOMMENDATIONS

## 164 6. Conclusion

165 The goal of this study to provide energy efficiency of the urban wastewater treatment sector  
166 in Turkey is to transform carbon footprint generating from fossil fuels into a neutral  
167 structure. The recommendations in the field of urban wastewater treatment are also included  
168 aimed at designing and operating criteria for energy consumption, increasing the energy  
169 efficiency of wastewater treatment plant, and reducing CO<sub>2</sub> emissions. At the same time, it is  
170 expected to benefit from this study that the sustainable investments on the basis of energy  
171 efficiency to be made to the urban wastewater treatment system facilitate given a consistent  
172 standard. As a result of this process, having detected the measures for energy efficiency is  
173 one of the important outcomes obtained in wastewater treatment industry. Another important  
174 issue for the implementation of energy efficiency measures in wastewater treatment industry  
175 is to ensure cooperation among the main stakeholders. In this regard, all stakeholders are  
176 substantially required to commitments to go to reduce in energy consumption. Furthermore,  
177 it should not be prohibitive nature of necessary legislation regarding the implementation of  
178 measures for energy efficiency [9]. The construction and operation of wastewater treatment  
179 plants are processes that require a high cost. Therefore, the most suitable process to be  
180 able to minimize construction and operation costs in the feasibility reports of the treatment  
181 plants must be selected. The facility should also be built with the appropriate mechanical  
182 equipment to process. Yuregir Wastewater Treatment Plant of Adana Metropolitan  
183 Municipality is a plant operating with activated sludge system. High energy - operating costs

**Comment [18]:** Please discuss / mention challenges faced , like

As with all major projects, a technical and financial analysis will determine the feasibility of a CHP project. However, even when such analysis is positive, operating a biogas CHP has challenges. In a 2011 U.S. EPA and Combined Heat and Power Partnership report, *Opportunities for Combined Heat and Power at Wastewater Facilities: Market Analysis and Lessons from the Field*, phone interviews were conducted with operators at 14 WRRFs using biogas CHP. Operators were asked about specific benefits and challenges they encountered.

2. The tentative challenges are as under ;
  - a. Gas Flow Measurement.
  - b. Low Flow Velocity  
Digester gas flow velocities change, sometimes only reaching low rates, so flow meters must have both low-velocity sensitivity and wide turndowns.
  - c. Temperature Changes  
Most wastewater treatment facilities are outdoors and affected by seasonal weather changes. Flow meters must be able to provide reliable data in extreme weather environments.
  - d. Other Environmental Factors
  - e. Wet, Dirty Gas
3. Therefore, please give comments on the above mentioned challenges which make this paper more conclusive

**Comment [19]:** Conclusion and recommendations be given under separate headings . Conclusion should be brief overview of the entire research proceedings

184 in applying the activated sludge treatment plant is known. However, this system that can  
185 meet the high flow rate for small volumes was deemed appropriate for Yuregir Wastewater  
186 Treatment Plant. As a result of research findings obtained from the plant; the removal  
187 efficiency for the whole plant was found maximum with the average average of 67,53% in  
188 February 2017 while the annual average was found to be 49,72% . Energy expenditure of  
189 305174 kWh/m<sup>3</sup> was determined by taking the monthly average energy consumption of the  
190 plant. Likewise; energy expenditure for 1 m<sup>3</sup> was calculated as 0,253 kWh by taking into  
191 account of the plant with the daily average flow and the total energy consumption. According  
192 to average daily flow from the plant and equivalent population, per capita water consumption  
193 of 4276 liters / month was found. The amount of energy expended per person per month in  
194 wastewater treatment was found to be 1083 W according to the total energy consumption  
195 used in the plant and the population equivalent value of the project. In accordance with data  
196 obtained from the plant, the unit energy consumption is reduced when organic loading is  
197 increased in the plant. It should not be much of effort to reduce organic pollution load to  
198 protect the plant from the negative factors and the increase of pollution per person in the  
199 future [10]. The awareness should be created about the opportunities and benefits to be  
200 derived from energy efficiency in the wastewater treatment field. The operation of  
201 wastewater treatment plants accordance with the principles of energy efficiency should also  
202 effectively be provided (operators training). Finally, the design and engineering firms  
203 operating in wastewater treatment field should be informed on the subject. Thus, the  
204 effective and efficient use of energy are supposed to be included in future projects.
