

**Efficacy of two (2) organic fertilizer sources (oil palm bunch and vermicasts)
on the growth response of *Tetrapleura tetraptera***

Abstracts

To increase awareness of *T. tetraptera* potential uses, enhance its utilization and promote its domestication as a fruit trees, a potential use of organic manure as soil amendment in afforestation, reforestation, agroforestry, fruit tree orchards, and bio-energy plantations cannot be over emphasized. Therefore, the study to determine the efficacy of organic manure (sole application and its interaction) on the growth of *Tetrapleura tetraptera* under a screen house condition was carried out in Federal College of Forest, Ibadan located within the government Reserve Area (GRA), Jericho Ibadan. . The experimental design was a 2 x 8 factorial arranged in a Completely Randomized Design (CRD) with seven (7) replicates each making a total of 112 experimental samples. The treatments used were as follows: vermicast at two levels (20t/ha, 40t/ha), oil palm bunch at two levels (20t/ha, 40t/ha), interaction of vermicast and oil palm bunch (1:1, 1:2 and 2:1) and Control (no amendment). . Data on plant height number of leaves, collar diameter and dry matter yields were generated and subjected to analysis of variance and significant means separated using Duncan's Multiple Range Test at 5 % level of significance. The results shows that, the collar diameter of *Tetrapleura tetraptera* increased (P=0.05) with the sole application of oil palm bunch at 40t/ha with a mean value of 2.16mm , however, this increase can also be comparable to the sole application of oil palm bunch at 20t/ha with a mean value of 2.04mm. Oil palm bunch at 20t/ha recorded the highest plant of *Tetrapleura tetraptera* with a mean value of 18.00cm while the interaction of VC+OB (2:1) and VC 40t/ha are also relatively comparable to the control (no amendment) to improve the plant height. The highest leaves number was observed when oil palm bunch 20t/ha was used as an amendment with a mean value of 14.0 while the lowest number of leaves was recorded with the interaction VC+OB 1:1 with a mean

29 value of 12.0. From the results obtained, oil palm bunch residue as an organic fertilizer improves
30 the growth of *Tetrapleura tetraptera*.

31 Key word: *Tetrapleura tetraptera*, oil palm bunch (OB), vermicast (VC), growth parameters

32

33 **Introduction**

34 The use of wild fruit trees as food and medicine is a popular practice in developing economies
35 like rural Africa (Kehlenbeck *et al.* 2013) and some parts of Asia (Joshi *et al.* 2018). This
36 practice is further facilitated by cultural beliefs, rural poverty and high cost of conventional
37 health care. For instance, several indigenous fruit trees such as *Tamarindus indica*, *Garcinia*
38 *buchananii*, *Canarium schweinfurthii* and *Tetrapleura tetraptera* have been reported to be useful
39 for food and medicine, especially in communities with limited health facilities (Katende *et al.*
40 1995; Okullo *et al.* 2014; Ranaivoson *et al.* 2015). However, *Tetrapleura tetraptera*, with its
41 sweet tasty fruit pulp and pleasant aroma which makes it suitable for food and beverage
42 flavouring (Ogbunugafor *et al.* 2017), seems to have received less attention in social economic
43 research compared to other indigenous fruit tree species. Despite its medicinal and nutritional
44 potential, *T. tetraptera* local use in the various communities where it is native has not been well
45 documented. Most studies have focused on the chemical and pharmacological properties of *T.*
46 *tetraptera* fruit (Abugri and Pritchett 2013; Lekana-Douki *et al.* 2011), with limited information
47 on its local applications, scientific findings indicate the medicinal and nutritional properties of
48 fruit trees, which is vital for rural livelihood sustainability.

49

50 Waste is an inevitable by-product of human actions. Better financial conditions and
51 life style in some part of the world had increased the quantity and density of
52 generated waste. Agro-industrial waste disposal is a main problem in many industries
53 around the world. The disposal of industrial wastes in the nearby areas causes
54 environmental dangers. The recycling of wastes is a disposal mechanism and resource
55 management. China harvests the biggest quantities of agriculture waste and crop
56 residues followed by India in the Asian and Pacific region (ESCAP 1997). Nutrient
57 requirement of crops by organic manures as compost resulting from agro-industrial

58 wastes is a major source of soil fertility and crop productivity which reduces use of
59 chemical fertilizers (Kayikcioglu 2013).

60
61 Organic manure contribute to the fertility of the soil by adding organic matter and nutrients such
62 as nitrogen, phosphorus and potassium amongst others, that are utilized by bacteria, fungi and
63 other organisms in the soil (Mattar,2000). Higher organisms then feed on the fungi and bacteria
64 in a chain of life that comprises the soil food web. Its products are obtained after decomposition
65 of organic materials like plants and animal sources which replenishes the soil with essential
66 elements and add humus to the soil (Mattar, 2000).

67
68 Palm bunch refuse is the solid waste generated during the processing of oil palm fruits. In the
69 palm oil manufacture practice there is generally a surplus of by-product and the utilization pace
70 of these by-products is small particularly for palm oil mill effluent (Rupani *et al.* 2010)..
71 The better nutrient reuse will perk up soil fertility and sustainability of palm oil production.
72 Techniques available, such as normal composting, co-composting and vermicomposting are
73 being practiced however, have not been exploited in its full strength as huge quantity of palm
74 waste could be decomposed in short time and the compost made from oil palm waste could not
75 only be applied to palm plantations but also to various crops. This will ultimately eliminate the
76 synthetic fertilizers application (Embrandiri et al. 2013).

77
78 Vermicomposting is the term given to the process of conversion of biodegradable matter by
79 earthworms into vermicast (Abbasi and Ramasamy, 2001). In the process, a major fraction of the
80 nutrients contained in the organic matter is converted to more bioavailable forms. Application of
81 vermicomposting improves the soil structure by increasing porosity and reducing the bulk
82 density. It improves soil aeration, water-holding capacity, buffer capacity, and cation exchange
83 capacity of soil (Nada *et al.*, 2013). In addition, the vermicast is also reported to contain
84 biologically active substances such as plant growth regulators and have been shown to increase
85 growth of many plants (Tomati *et al.*, 1990, 1995; Abbasi and Ramasamy, 1999; Atiyeh *et al.*,
86 2002; Arancon *et al.*, 2004; Gajalakshmi and Abbasi, 2004; Edwards, 2004; Sinha, 2009).
87 Although a considerable number of studies have been carried out on vermicast and their impact
88 on the soil and plant growth (Gajalakshmi *et al.*, 2001a, 2002; Singh and Sharma, 2002;

89 Gajalakshmi and Abbasi, 2003, 2004; Padmavathiamma *et al.*, 2008), there is still a lack of
90 knowledge on the interaction with other organic materials. Therefore, this study was carried out
91 to determine the efficacy of organic manure (sole application and its interaction) on the growth
92 of *T. tetraptera* under a screen house condition.

93

94 **MATERIALS AND METHODS**

95 **Experimental site**

96 The experiment was carried out in Federal College of Forest, Ibadan located within the
97 government Reserve Area (GRA), Jericho Ibadan and South-West local Government area of Oyo
98 state. It lies on latitude 7°90'N and longitude 3°54'E, the climate pattern of the area is tropically
99 dominated by annual rainfall which ranges from 1,200-1,250 mm and average relative humidity
100 of about 37.2°C. The eco-climate of the dry season (usually commencing from November-
101 March) and the raining season start from April to October (FRIN, 2016).

102

103 **Procurements of materials**

104 The soil samples was collected from farm practical area (FAP), Federal College Forestry, Ibadan.
105 Top soil of 0 – 20 cm depth was be used for the experiment. The soil was air dried; grounded and
106 sieved using 2mm sieve to remove gravel and large plant roots. The soil samples was chemically
107 analyzed for nitrogen and other nutrient content. Two kilogram soil was weighed in a polythene
108 bag and incorporated with organic manure at different levels.

109 Vermicast was collected from the Fadama site at Forestry Research Institute of Nigeria (FRIN),
110 the vermicast was grounded into powdery form for easy application and weighed with sensitive
111 scale into varying levels. Oil palm bunch was collected from oil processing farm Gbongan, Osun
112 State. The oil palm bunches were dried, grounded and sieve with 2mm mesh and also weighed
113 by sensitive scale into varying levels

114 Seedlings of *Tetrapleura tetraptera* was collected from the mother tree from the wild at Eruwa
115 and raised in a germination basket for four (4) weeks , 112 healthy seedlings was selected from
116 the basket based on the uniform treatments and then transplanted into a 2kg pot of soil. Watering
117 was done regularly and data collection was taken every three (3) weeks on plants height, collar

118 diameter, number of leaves for a period of 18weeks while biomass was also done to determine
119 the wet and dry weight of the plants samples. The experimental design was a 2 x 8 factorial
120 arranged in a Completely Randomized Design (CRD) with seven (7) replicates each making a
121 total of 112 experimental samples. The treatments used were as follows: vermicast at two levels
122 (20t/ha, 40t/ha), oil palm bunch at two levels (20t/ha, 40t/ha), interaction of vermicast and oil
123 palm bunch (1:1, 1:2 and 2:1) and Control (no amendment).

124 **Data collection**

125 The following growth parameter of *Tetrapleura tetraptera* was taken

- 126 i) Plant height
- 127 ii) Number of leaves
- 128 iii) Collar diameter
- 129 iv) Dry matter yield

130 **Soil analysis**

131 Soil sample was analyzed for pre-planting and post-planting for the essential elements (Macro
132 and Micro nutrients).

133 **Statistical analysis**

134 Quantitative data will be analyzed using the ANOVA procedure and means separated using the
135 Duncan Multiple Range Test (DMRT) at 5% probability (SAS Institute, 2002).

136 **Results and Discussion**

137 Table 1: physical and chemical properties of soil, vermicast and oil palm bunch used for the
138 experiment.

Properties	Soil	Vermicast %	Oil palm bunch %
pH (1:1)	6.5	5.9	5.1
N %	0.86	1.02	1.72
P mg/kg	37.2	12.5	9.45
K %	0.13	3.47	32.1
Mg%	1.08	2.7	8.1

Fe %	425	310	2.11
Mn %	58.6	59.9	26.3
Zn %	3.56	14.4	3.40

139

140 Key: OC = Organic carbon, N = Nitrogen, P = Phosphorous, K = Potassium and Mg =
141 Magnesium, Fe = iron.

142 The soil is a sandy loam, moderately furnished with Zinc, high in phosphorus with low Nitrogen
143 and potassium. Vermicast used for the experiments was high in zinc, phosphorus and manganese
144 but relatively low in potassium when compared to the oil palm bunch which has a higher
145 potassium, Nitrogen and organic carbon.

146

2:1							

149

150 VC= vermicast: OB = oil palm bunch: VC+OB= interaction of vermicast and oil palm bunch

151 There was no significant difference ($p < 0.05$) in the plant height of *Tetrapleura tetraptera* among
152 all the treatments used across the weeks after transplanting except at 3WAT when the sole

153 application of vermicast ,oil palm as well as their various interactions were significantly higher
 154 ($p<0.05$) than the control (no amendment). Sole application of oil palm bunch (OB 40 t ha-1)
 155 and oil palm bunch (20 t ha-1) recorded the highest collar diameter in *tetrapleura tetraptera*
 156 plants with a mean value of 2.16mm and 2.04mm respectively which are also comparable to
 157 every other treatments used (sole application and it interactions) except the control (no
 158 amendment) that recorded the least collar diameter with a mean value 1.89mm at the 18th week
 159 of the experiment. This results corroborates with the research of (Baharuddin et al. 2011) who
 160 reported that oil palm bunch waste improves soil, enhances vigor and production.

161 Table 3: **Influence of organic amendments on the plant height of *Tetrapleura tetraptera***
 162 **under a greenhouse condition**

treatments	0WAT	3WAT	6 WAT	9 WAT	12 WAT	15 WAT	18 WAT
Control	7.7ab	9.2a	10.9a	12.6a	14.0a	15.5ab	17.0ab
VC 20t/ha	6.6b	8.2a	9.9ab	11.5ab	12.9ab	14.6b	16.7ab
VC 40t/ha	7.9ab	9.5a	11.0a	12.7aa	13.9a	15.2ab	17.3ab

2:1							

163

164 VC= vermicast: OB = oil palm bunch: VC+OB= interaction of vermicast and oil palm bunch

165 There was no variation among all treatments used. However, oil palm bunch at OB 20 t/ha was
 166 higher with mean value of 18.00cm as compared with other treatments used. The interaction of
 167 VC+OB (2:1) and VC 40t/ha are also relatively comparable to the control (no amendment) to
 168 improve the plant height. These result supports the findings of Canelles *et al* 2002) who stated
 169 that vermicast increases growth yield and also contain higher amount of nitrogen and also
 170 contain nitrifying power than the corresponding soil.

171

172

2:1							

175

176 There was no significant difference in all treatments used. At 18 WAT, all the treatments used
 177 were comparable. The highest leaves number was observed when OB 20t/ha was used as an
 178 amendment with a mean value of 14.0 while the lowest number of leaves was recorded with the
 179 interaction VC+OB 1:1 with a mean value of 12.0. The control plot did relatively well and it is
 180 comparable to the sole application of vermicast at 20t/ha and 40t/ha as well as their interactions
 181 at (VC+OB 1:2 and VC+OB 2:1).

182

183

184

185

186

187

188 Table 5: **Dry matter yield**

Treatments	shoot	Leaves	Root
Control	149.7	146.5	84.6
VC 20t/ha	88.3	163	87.5
VC 40 t/ha	63.1	210	97.2
OB 20 t/ha	95.6	164	81
OB 40 t/ha	120.4	235.2	171.4
VC+ OB 1:1	130.7	212	126
VC+ OB 1:2	88.3	158.4	103.0
VC+ OB 2:1	82.3	195	89.8

189

190 There was no variation in the dry matter yield. The highest dry matter yield was recorded for oil
 191 palm bunch at 40t/ha and it is comparable to other treatments used including the control the
 192 interaction of VC+ OB 2:1 was relatively low compared to other treatments for the shoot while
 193 OB 20 t/ha had the lowest in root.

194 **Conclusion**

195 Sole application of oil palm bunch at 40t/ha and 20t/ha proves effective for the enhancement of
 196 the growth parameters (height, collar diameter) of *Tetrapleura tetraptera* .The plants height and
 197 the collar diameter of *Tetrapleura tetraptera* increased (P=0.05) with the sole application of oil
 198 palm bunch at 40t/ha, although this increase can also be comparable to the sole application of oil
 199 palm bunch at 20t/ha and comparatively higher than the control treatment. For the number of
 200 leaves, the control plot did relatively well and it is comparable to the sole application of
 201 vermicast at 20t/ha and 40t/ha as well as their interactions at (VC+OB 1:2 and VC+OB 2:1). The
 202 enhanced plant growth in soil supplemented with palm bunch as observed in this study may be
 203 attributed to the important role played by the organic supplement in supplying the available plant
 204 minerals and in providing favorable condition for microbial activity as well as providing better

205 soil conditions (Omoti *et al.*, 1999). Therefore the potential of oil palm bunch residue should be
206 harnessed by agro allied industries.
