

1 **ANTHROPOMETRIC PARAMETERS AFFECTING OCULAR AXIAL LENGTH**
2 **IN NIGER DELTA REGION OF NIGERIA.**

3
4
5 **Abstract**

6 **AIM:** To determine the anthropometric parameters affecting ocular axial length in Niger
7 Delta region of Nigeria.

8 **METHOD:** This was a community based descriptive study carried out in Port Harcourt City
9 LGA, Nigeria using a multistage random sampling technique. Inclusion criteria were Visual
10 Acuity > 6/18, age greater than 18 years and no history of past ocular surgeries or trauma.
11 Socio demographic data was obtained through an interviewer based proforma and included
12 age, sex and tribe. Anthropometric parameters were measured using a standard height and
13 weight automated scale (SECA 769,220). Ocular examinations done included visual acuity,
14 applanation tonometry, and ophthalmoscopy. Axial length (AL) was measured using
15 Amplitude (A) scan ultrasonography (SONOMED PACSCAN 300AP). Data obtained from one
16 eye of the subjects were analyzed using SPSS (Version 17), and p value was set at ≤ 0.05 .

17
18 **RESULTS:** The study was made up of two hundred and twelve (212) males (45.5%) and two
19 hundred and fifty four (254) females (54.5%) with M: F ratio of 1:1.2 giving a total of four
20 hundred and sixty six (466) subjects. The age range was 18-92 years and mean age of the
21 subjects studied 43.0 ± 14.2 years. Findings revealed mean AL, Height and Weight to be
22 (23.2 ± 1.0 mm), (162.5 ± 9 cm) and (70.5 ± 14.8 kg) respectively. The mean AL was greater in
23 males than females. There was a statistically significant relationship between height and AL
24 in both gender with AL increasing by 0.035mm ($p=0.001$, $r=0.261$) with one centimeter
25 change in height in males and 0.025mm ($p=0.001$, $r=0.2680$) in females. There was also a
26 statistically significant (0.009mm) increase in AL per one kilogram change in weight in
27 females ($p=0.0001$, $r=0.188$).

28
29 **CONCLUSION:** This study noted that there are significant relationships between AL and
30 height and weight respectively. This could add to the data bank for AL in the country and
31 form a basis for identifying deviations from the normal, for further research.

32
33 Keywords: Anthropometric Parameters, Ocular Axial Length, Niger Delta

34 Introduction

35 Axial length is defined as the distance between the anterior and the posterior poles of the eye
36 or as the distance from the anterior curvature of the cornea to the retinal pigment epithelium
37 in alignment along the optical axis of the eye.^{1,2,3} [1,2,3]. It is an important biometric parameter
38 in the eye whose measurement using the amplitude scan is the “Gold standard” in
39 ophthalmology.⁴ [4]. This is important in several conditions including the determination of the
40 refractive status of the eye as well as determination of intraocular lens power for patients prior
41 to cataract surgery. At birth, the axial length is approximately 17-18mm; following which it
42 increases by about 5mm (up to 23mm) from birth to age 3- 6years until it reaches an average of
43 24mm in adulthood.¹ [3]. Mean axial length in the Blue mountain eye study,¹ [4], was
44 23.44mm, values noted for the Tanjong Pagar study,⁵ [5], in China was 23.23mm, while that
45 gotten by Adio et al,⁶ in Nigeria was 23.57mm±1.19 which is in agreement with previously
46 documented literature. It has been found from previous studies, to be affected by age, sex and
47 educational status,^{7,8,9} including several ocular factors such as refractive error, anterior
48 chamber depth, corneal curvature and central corneal thickness.^{10,11,12,13} [10,11,12,13]. Previous
49 studies have also shown a relationship between short axial length of the eye and an increased
50 incidence of retinal vein occlusions,¹⁴ [14], primary angle closure glaucoma,¹⁰ [10], and
51 hypermetropia while longer axial lengths have been noted to be associated with an increased
52 incidence of cataracts,¹⁵ [15] and myopia. Axial length is also said to have an influence on
53 emmetropisation of the eye.¹⁶ It is also the most important parameter in the calculation of
54 intraocular lens power prior to cataract surgery, and helps in the diagnosis of pathological
55 conditions like staphyloma and risk of retinal detachment.¹ [7].

56 Therefore there is a need to know the normal values of the axial length in our environment and
57 how it is affected by height and weight. This can subsequently be used as a yardstick to detect
58 those with abnormal values, and subsequently screen them for the associated pathological
59 conditions.

60 The axial length is the most important anthropometric variable in the calculation of Intra ocular
61 Lens power as a 0.1mm error in its measurement will result in as much as 0.25D change in
62 post-operative refraction.¹⁷

63 Several studies have explored the association of axial length with both ocular and systemic
64 parameters; Ojaimi et al,¹⁸ studied the effect of stature and anthropometric parameters on eye
65 size and refraction in a population based study of Australian children with mean age of 6 years
66 measured height, weight and waist circumference using a standardized protocol. After
67 adjustment for age in weeks, height was found to be strongly associated with Axial length

68 although other parameters were not associated with AL. In contrast, Osuobeni et al,¹⁹ who
69 studied the effects of physical size on refractive error and optical component dimensions in
70 sickle cell disease (SCD) patients noted that, the height correlated positively with axial length
71 although this correlation was lost after adjustments for age and gender. This variation in the
72 findings as compared with the previous study might have been brought about by the fact that
73 SCD patients have some form of stunted growth from chronic ill health as well as less body fat
74 than normal for their age and sex.

75 In the Reykjavik Eye Study²⁰, height correlated positively with axial length using multivariate
76 analysis (p-value< 0.01) but there were no correlations between axial length and other
77 parameters. The strengths of this study as pointed out by the author include the fact that it was
78 a homogenous large population based cross sectional study.

79 Ojaimi et al¹⁸, in Australia noted the effect of stature and other anthropometric parameters on
80 eye size and refraction stating that height correlated positively with axial length.

81 In another study by Pereira et al²¹, on ocular biometry noted that a positive correlation was
82 established between axial length and height. Similarly, the Meiktila Eye Study²², in central
83 Myanmar, reported that height and weight were significantly correlated with age, gender and
84 all the ocular biometric parameters even after adjusting for age and gender. Taller and heavier
85 persons had eyes with longer axial lengths and deeper anterior chambers.

86 Multivariate analysis showed consistent results with the findings for associations between
87 height, weight and ocular biometry. These results were consistent with results of the Beijing
88 Eye Study²³, which was also a population based study of 3251 subjects aged above 40 years.
89 This study was carried out to determine whether anthropomorphic measurements were
90 associated with ocular and general parameters and it was discovered on multivariate analysis
91 that there was a significant association between axial length and higher age, higher body height
92 and level of education.

93 Axial length is an important anthropometric parameter in relation to the eye, if our data is in
94 agreement with that of other studies and relationships do exist with height and weight, it
95 would form a basis for identifying deviations from the normal, for further research, and also
96 add to the data bank for axial length.

RESULTS

Four hundred and sixty six (466) subjects from the general adult population were studied.

Axial Length (AL) values in one randomly selected eye of the population studied were analysed.

The mean age of the subjects studied was 43.0 ± 14.2 years with the age distribution between 18 and 91 years, and a peak age group of between 31 and 40 years as shown in Figure 1.

The mean age for males was 41.6 ± 12.7 years and that for females 44.8 ± 15.8 years.

There were two hundred and twelve (212) males (45.5%) two hundred and fifty four (254) females (54.5%) with male to female ratio of 1: 1.2.

The gender distribution for different ages is shown in Table 1. About one quarter of the males in the population studied, ($n=54$; 25.5% of total male population) were within 41 and 50 years and majority of the female population ($n=83$; 32.6% of female population) were within 31 and 40 years. There was a significant difference between both genders at different age groups ($p=0.01$).

In the general population studied, a positive relationship was found between axial length and height ($r=0.351$, p -value 0.0001) that for every 1cm increase in height, AL rises by 0.039mm (0.030 to 0.048mm at a constant value of 16.909) given an hypothetical equation for AL estimation from height. Figure 2.

There was a statistically significant positive relationship between height and axial length in both male and female population as shown in Figure 3 and 4. This showed that axial length increased with every one centimetre increase in height by 0.035mm (CI 0.018 to 0.052) in males and 0.025mm (CI 0.014 to 0.036) in females.

There was a statistically significant positive relationship between weight and axial length in female population but no relationship was found in males as shown in Figure 5 and 6. Among the female population it was found that for every one kilogramme increase in weight the AL increased by 0.009mm (CI 0.003 to 0.015).

179 **Discussion**

180 This study describes anthropometric parameters affecting ocular axial length in Niger Delta
181 region of Nigeria. This could add to the data bank for AL in the country and form a basis for
182 identifying deviations from the normal, for further research.

183 Most of the subjects studied were of Rivers ethnicity (n=184; 39.5%) which could be explained
184 by the fact that the study was carried out in the communities that make up Port Harcourt city
185 LGA. This was similar to the study carried out by Adio,⁶ on 400 subjects in UPTH eye clinic
186 where 56% of the subjects were from Rivers state.

187 The mean axial length of the population in this study was 23.2±1.0mm which was similar to the
188 values noted by Connell et al,²⁴ (23.03±1.61mm), Hashemi et al,⁷(23.14mm) and other eye
189 studies,^{25,26} (23.25±1.14). It was however slightly lower than that obtained by Adio et al
190 (23.57±1.19 mm), and Iyamu et al,¹³(23.5±0.70mm). This difference may have been attributed
191 to the fact that the former was a hospital-based study and may not have been representative of
192 the population.

193 The mean height in this study was 162.5±9cm, and males were noted to be significantly taller
194 than females (p=0.0001). This was similar to the values noted in the Brazilian study by Pereira
195 et al,²¹(160.26±8cm) but was notably lower than the mean values of height noted in the
196 Reykjavik eye study (176cm) although in the latter study, males were also found to be
197 significantly taller than females. The difference in the height may not be unrelated to the fact
198 that the Reykjavik eye study was carried out among Scandinavians who are taller than the
199 Nigerians in this study population. Conversely the mean height in this study was lower than that
200 noted in the Central India eye study,¹(156±9cm).and may have been due to the difference in
201 body stature between the two study populations.²⁴

202 The mean weight in this study was 70.5±14.8kg with no significant difference in both genders.
203 (p=0.898), this was also lower than the mean weight in the Reykjavik eye study (77.5kg).
204 Although in the latter, males were also noted to be heavier than females.

205 The statistically significant relationship between axial length and height noted in this study as
206 shown in figs 2, 3 and 4 was similar to that noted on regression analysis in the Epic Norfolk
207 study,⁹ which stated that for every increase in height of 8cm, there is an attendant increase in
208 axial length of 0.21mm. This was also the case in the study by Pereira et al,²¹ where every 10cm
209 increase in height was associated with a 0.32mm increase in axial length and the study on
210 Mongolians by Uranchimeg et al,²⁷ where every 10 centimeter increase in height was associated
211 with a 0.27mm increase in axial length. Following the same trend, the Central India eye
212 study,¹ also noted a 0.23mm increase in axial length for every 10cm rise in height. Similarly, in

213 the Reykjavik study,²⁰ height was noted to correlate positively with axial length. This trend was
214 however not noted in the study by Osuobeni et al,¹⁹ where the relationship between axial
215 length and height was lost after corrections for age. This difference in the relationship between
216 axial length and height in this study may likely have been due to the fact that this latter study
217 was carried out among sicklers with average height attained reduced due to the chronic nature
218 of the illness and thus not comparable.

219 A statistically significant relationship was noted between axial length and weight in only the
220 female gender. This relationship was however not noted in the male gender (Figs 5, 6). This is
221 similar to results noted in the Reykjavik study,²⁰ where weight was said to be unrelated to all
222 ocular parameters. The Epic-Norfolk study noted a relationship between axial length and
223 weight, but majority of the studies did not show a relationship between axial length and
224 weight.

225 **Conclusion**

226 This study noted that there are significant relationships between AL and height as well as
227 weight respectively. This could add to the data bank for AL in the country and form a basis for
228 identifying deviations from the normal, for further research.
