

**Analytical Hierarchy Process (AHP) Model for Prioritizing Alternative Strategies for Malaria Control**

**ABSTRACT**

**Aim:** This study Analytical Hierarchy Process (AHP) Model for Malaria Control” was aimed at using analytical hierarchy process model to prioritize alternative strategies for malaria control.

**Place and the Duration of the Study:** The study was carried out in Bauchi State, Nigeria from May, 2017 to June, 2019.

**Methodology:** The study used primary and secondary data. The secondary data were the identified alternatives strategies for malaria control and the criteria for evaluating these strategies obtained from malaria control journals and World Health Organization report. The criteria and malaria control strategies were used as input for developing a 9-point scale used in a questionnaire to obtained responses from the Experts in scoring the pairwise comparison of the criteria and the alternatives. Analytical hierarchy process (AHP) model was used to develop the pairwise comparison matrices from the Experts opinions. Computations were carried out with the help of computer software, business performance management Singapore (BPMSG-AHP ONLINE).

**Results:** The result of the analysis shows that the use of insecticide treated nets was ranked the best strategy for malaria control (AHP score 0.348). Based on the findings of this paper, it is recommended that the use of treated mosquito net should be given much attention in controlling malaria in Nigeria.

**Conclusion:** We therefore conclude that in a multi -criteria decision making situation, AHP is a powerful tool to assists decision makers

**Keywords:** Analytical Hierarchy Process; Multi-criteria Decision Analysis; Alternative; Strategy; Malaria Control

**1.0 Introduction**

Decision making is one activity that we can't do without. In all aspects of our lives we are confronted with challenges that we need to make a decision. Decision may be simple or complex depending on the scenario and factors responsible.

According to Alexander [1], modern day decision has been inherently complex when many factors have to be weight against competing priorities. Decision making involves the use of intelligence, wisdom and creativity in order for humans to satisfy basic need or to survive. Evaluating a decision requires several considerations such as the benefits derived from making the right decision, the cost, the risk and losses resulting from the action taking if the wrong decision is made.

Some useful techniques in multi criteria decision analysis (MCDA) are goal programming, multi-attribute utility theory (MAUT) and analytical hierarchy process (AHP). AHP has been increasingly applied as a technique for MCDA in the field of healthcare [2].

AHP is a decision-making method that was developed by Saaty, the technique used to organize complex relationships between elements into structure or system based on subjective judgment such as experience [3].

49 AHP is a theory of measurement through pairwise comparisons and relies on the  
50 judgment of experts to derive priority scales [4]. It is one of the more popular methods of  
51 MCDM and has many advantages as well as disadvantages. One of its advantages is its ease  
52 of use. Its use of pairwise comparison can allowed decision makers to weight coefficient and  
53 compare alternatives with relative ease. It is scalable, and can easily adjust in size to  
54 accommodate decision making problems due to its hierarchical structure. And although it  
55 requires input data to properly perform pairwise comparisons, the data are rather easy to  
56 obtain. The method has experience problems of interdependence between criteria and  
57 alternatives. Due to the approach of pairwise comparisons, it can also be subjective to  
58 inconsistencies in judgment and therefore the question of reliability of the result arises and  
59 so, to evaluate the reliability of the obtained result, it is reasonable to find dependency  
60 between result of the AHP and inaccuracies of the initial data-Experts judgement [5].

61 AHP is an Eigen value approach to the pairwise comparisons. It also provides a  
62 methodology to calibrate the numerical scale for the measurement of quantitative as well as  
63 qualitative performances. The scale ranges from 1/9 for least valued than to 1 for equal and to  
64 9 for absolutely more important than covering the entire spectrum of the comparisons. Some  
65 key and basic steps involves in this methodology are: 1. State the problem. 2. Broaden the  
66 objectives of the problem or consider all actors, objectives and is outcome. 3. Identify the  
67 criteria that influence the behaviour. 4. Structure the problem in a hierarchy of different levels  
68 constituting goals, criteria, sub-criteria and alternatives. 5. Compare each element in the  
69 corresponding level and calibrate them on the numerical scale. This requires  $\frac{n(n-1)}{2}$   
70 comparisons, where n is the number of element with the considerations that diagonal  
71 elements are equal or 1 and the other elements will simply be reciprocals of the earlier  
72 comparison. 6. Perform calculations to find the maximum Eigen value, consistency index  
73 (CI), consistency ratio (CR) and normalized values for each criteria /alternative. 7. If the  
74 maximum Eigen value, (CI), and (CR) are satisfactory then decision is taken based on the  
75 normalized values; else the procedure is repeated till these values lie in the desired range [6].

76 Analytical hierarchy process has been applied in so many studies, including  
77 Prioritization of Evacuation of Solid Waste at Municipal Solid Waste Disposal Center [7];  
78 Analysis of Poverty and Inequality Among Farmers in Yola North Local Government Area of  
79 Adamawa State Nigeria [8]; Analytical Hierarchy Process Modelling for Malaria Risk Zone  
80 in Vadora District, Gujrat[9]; A systematic literature review and evaluation shows that more  
81 than two hundred studies were carried out in which the AHP was applied.

82 Management and planning for implementation of alternative strategies to control  
83 malaria can be considered to take place in a multi-criteria environment. The application of  
84 MCDA in healthcare shows that the techniques are also suitable to malaria control. In  
85 healthcare, certain problems carry quantitative features which can be evaluated numerically,  
86 however others carry qualitative features that are complex to evaluate numerically, AHP can  
87 assist in assigning priorities and weight [10].

88 Malaria control and prevention seem to have followed a slow lane in spite of many  
89 years of intervention programmes. Strategies to control malaria includes vector control which  
90 reduces transmission by the mosquito vector from humans to mosquitoes and then back to  
91 humans (this is achieved using insecticide treated mosquito nets or indoor residual spraying);  
92 chemoprevention which prevents the bloodstage infections in humans; case management  
93 which includes diagnosis and treatment of infections [11]; spraying breeding sites with  
94 dichlorodiphenyltrichloroethane (DDT); intermittent preventive treatment [12]; and other  
95 personal protection measures such as use of repellents on exposed skin and clothes , wear  
96 long pants, long-sleeves shirt and a hat, and staying indoors behind the screen entries. The  
97 followings are also identified by World Health Organization as strategies to roll back malaria:  
98 evidence based decision using surveillance, appropriate responses and building community

99 awareness; focus research to develop new medicines, vaccines and insecticides as well as to  
100 enhance epidemiological operational research activities; coordinated action for strengthening  
101 existing health services, policies and providing technical support and harmonized actions to  
102 build a dynamic global movement through partnership.

103 In spite of many years of intervention programmes, malaria control and preventions  
104 seem to follow slow lane. Many studies were carried out to prevent infection and the spread  
105 of the disease. Alternative strategies for malaria control were provided without prioritizing  
106 them. The society need to know the strategy that experts consider more efficient in malaria  
107 control in order to give more attention to it. There is therefore the need to prioritize these  
108 alternative strategies and identify the one with the highest priority so that more effort will be  
109 geared towards that and more resources will be channelled in that direction.

110 The aim of this study is to use Analytical Hierarchy Process (AHP) model to prioritize  
111 alternative strategies for malaria control in Bauchi State, Nigeria.

112

## 113 2.0 Material and Methods

114 Primary and secondary data were both used in this study. Questionnaire was designed  
115 and administered to experts (medical personals in various healthcare units of Bauchi State) to  
116 obtain the relative importance of each alternative and criteria over the other.

117 The secondary data was obtained from world health organization reports on malaria  
118 and other journals on malaria control preventions. Interviews were also conducted to identify  
119 the malaria strategies practice in the study area. The major malaria control strategies  
120 (alternatives) and criteria were identified. The following were identified as the goal,  
121 alternatives and criteria to malaria control in the study area.

122

123 **Figure 1: The hierarchical structure of the problem.**

124

129

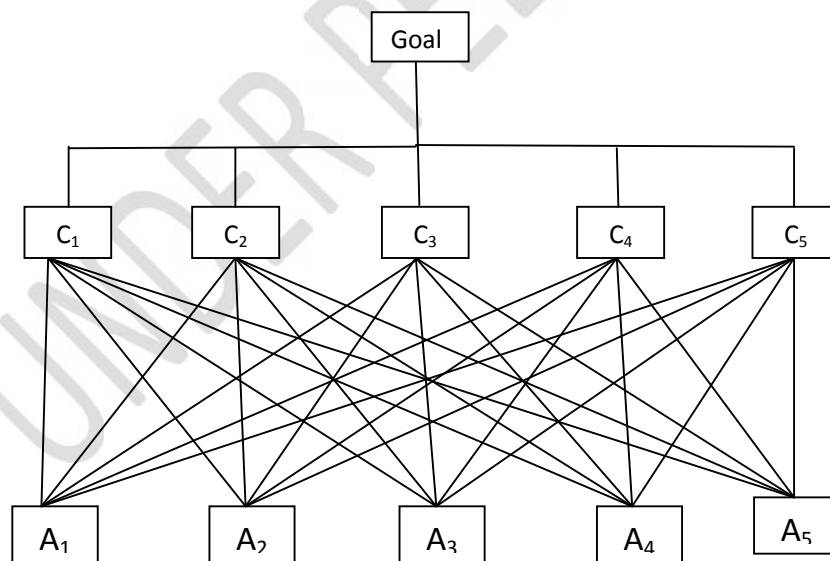

130

131

132

133

134

135 **G = GOAL;** Control malaria in Bauchi

136 **ALTERNATIVES:** - The following were identified as major alternatives to malaria control

137  $A_1$  = Insecticide treated net (ITN)/ long lasting insecticidal net (LLIN).

138  $A_2$  = Indoor residual spraying (IRS)

- 139  $A_3$  = Larval source management (LSM)  
 140  $A_4$  = Intermittent preventive treatment of pregnant women and children under five.  
 141  $A_5$  = Providing quality assured treatment to all patients.

142 **CRITERIA:** The following were the criteria identified:-

- 143  $C_1$  = Accessibility  
 144  $C_2$  = Affordability  
 145  $C_3$  = Availability  
 146  $C_4$  = Acceptability  
 147  $C_5$  = Convenient

148 **2.1 Method of Analysis**

149 The Saaty analytic hierarchy process model was adopted for this study. The problem  
 150 was decomposed into objective, alternatives and criteria.

151 Based on the pairwise comparison of the alternatives and criteria that was obtained  
 152 from the Experts, matrices were formed. The entries in the matrices were based on the verbal  
 153 judgment of the Experts. In order to designate the importance of each parameter; we  
 154 weighted them using a pairwise comparison method which is one of the component of AHP.  
 155 To assist in the weighing method of the pairwise matrix, the Saaty's pairwise comparison  
 156 table was used. This was carried out by asking the Experts to select which alternative is more  
 157 important than the other with respect to a given criterion and to state how much important. A  
 158 table of intensity of importance was provided to guide the Experts.

159 **Table 1: The Fundamental Scale of Absolute Numbers.**

Intensity of Importance	Definition	Explanation
1	Equal importance	Two activities contribute equally to the objective
2	Weak or slight	Experience and judgment slightly favour one activity over another
3	Moderate importance	Experience and judgment slightly favour one activity over another
4	Moderate plus	Experience and judgment slightly favour one activity over another
5	Strong importance	Experience and judgment strongly favour one activity over another
6	Strong plus	Experience and judgment strongly favour one activity over another
7	Very strong or demonstrated importance	An activity is favoured very strongly over another, its dominance demonstrated in practice.
8	Very, very strong	The evidence of favouring one activity over another is of the highest possible order of affirmation
9	Extreme importance	The evidence of favouring one activity over another is of the highest possible order of affirmation

160 Source: Saaty (2008)

161 The table of pairwise comparison was constructed for each criterion. This was done to  
 162 compare each alternative against the other with respect to the given criterion. Another matrix

163 was again constructed to obtain the relative weights for each criterion with respect to the  
164 goal.

## 165 2.2 Ranking of criteria and alternative

166 Eigenvector solution approach was used for ranking of priorities from a pairwise  
167 matrix. The ranking  $P_i$  of alternative  $A_i$  is calculated using the following formula (weighted  
168 sum model);

$$169 P_i = \sum_{j=1}^n a_{ij}w_j \quad (1)$$

170 With  $w_j$ , the weight of criterion  $C_j$ , and  $a_{ij}$  the performance measure of alternative  $A_i$  with  
171 respect to criterion  $C_j$ , performance values are normalized.

## 172 2.3 Consistency of the comparison matrix.

173 Consistency implies coherent judgment on the part of the decision maker regarding  
174 the pairwise comparisons. Mathematically, we say that a comparison matrix  $A$  is consistent if

$$175 a_{ij}a_{ik} = a_{jk} \text{ for all } i, j \text{ and } k \quad (2)$$

176 This property requires all the columns (and rows) of  $A$  to be linearly dependent.

177 It is usual for all comparison matrices to be consistent. Indeed, given that human  
178 judgment is the basis for the construction of these matrices, some “reasonable” degree of  
179 inconsistency is expected and tolerated.

180 To determine whether or not a level of consistency is “reasonable” we need to  
181 develop a quantifiable measure for the comparison matrix  $A$ . If  $A$  is perfectly consistent it  
182 will produce a normalized matrix  $N$  in which all the columns are identical – that is, given that  
183  $w$  is a column vector of the relative weight  $w_i, i = 1, 2, \dots, n, A$  is consistent if,

$$184 Aw = nw \quad (3)$$

185 For the case where  $A$  is not consistent, the relative weight,  $w_i$  is approximated by the  
186 average of the  $n$  element of row  $i$  in the normalized matrix  $N$ . Letting  $\bar{w}$  be the computed  
187 average vector it can be shown that

$$188 A\bar{w} = n_{max}\bar{w}, n_{max} \geq n \quad (4)$$

189 In this case, the closer  $n_{max}$  is to  $n$ , the more consistent is the comparison matrix  $A$ .  
190 Base on this observation, AHP computes the consistency ratio as

$$191 CR = \frac{CI}{RI} \quad (5)$$

$$192 CI = \text{Consistency index of } A = \frac{n_{max} - n}{n - 1} \quad (6)$$

$$193 RI = \text{Random consistency of } A = \frac{1.98(n-2)}{n} \quad (7)$$

194 The random consistency index,  $(RI)$ , was determine empirically as the average  $CI$  of  
195 a large sample of randomly generated comparison matrices,  $A$ .

196 If  $CR = .1$ , the level of inconsistency is acceptable, otherwise, the inconsistency is  
 197 high and the decision maker may need to re-estimate the element  $a_{ij}$  of  $A$  to realize better  
 198 consistency.

199 We compute the value of  $n_{max}$  from  $A\bar{w} = n_{max}\bar{w}$  by noting that the  $i$ th equation is

$$200 \sum_{j=1}^n a_{ij}\bar{w}_j = n_{max}\bar{w}_i, i = 1,2,3 \dots, n \quad (8)$$

$$201 \text{ Given } \sum_{i=1}^n \bar{w}_i = 1, \quad (9)$$

202 we get

$$203 \sum_{i=1}^n (\sum_{j=1}^n a_{ij}\bar{w}_j) = n_{max} \sum_{i=1}^n \bar{w}_i = n_{max} \quad (10)$$

204 This means that the value of  $n_{max}$  can be determined by first computing the column vector  
 205  $A\bar{w}$  and the summing up its elements.

### 206 3.0 Data Analysis

207 This chapter presents the results of the analysis done on Experts' opinion on the best  
 208 alternative strategy to malaria control using the identified alternatives and criteria.

#### 209 3.1 Presentation of Tables and Results

210 The following pairwise comparison matrices were obtained based on Experts' verbal  
 211 judgments of the criteria and the alternatives. The normalization matrices and results of Table  
 212 2 to Table 5 are the results of analyzing each of these matrices.

213 **Table2: Pairwise Comparison and Normalization Matrix for the Criteria**

A <sub>5</sub>	0.108	5	0.106	5	0.104	4	0.120	4	0.086	4	0.106	5

223

224 It can be observed in **Table 2 and Table 3** that the value of the consistency ratio **(CR)**

225 is less than 0.10, which means all the matrices are within acceptable range.

### 226 3.2 Overall Priority Vector

227 The final Priority vector was obtained by multiplying the priority vectors of the  
228 criteria by the priorities for each alternative for each objective.

229 In Table 5 the priorities (Prio.) and the rank (Rnk) for each alternative with respect to  
230 each criterion has been calculated.

231 Based on the results of **Table 4 and Table 5**, the best alternative strategy for malaria  
232 control was A<sub>1</sub> (Insecticide treated nets).

233

234

#### 235 **4.0 Conclusion**

236 Analytical Hierarchy Process (AHP) Model for Prioritizing Alternative Strategies for  
237 Malaria Control was carried out in Bauchi State, Nigeria. If the priority orders can be  
238 followed as identified in the study the use of insecticide treated net should be given high  
239 priority in the effort to prevent and control the spread of malaria in Nigeria. If the results of  
240 the study would be implemented the problem of malaria spread and control will be minimized  
241 greatly. We therefore conclude that in a multi -criteria decision making situation, AHP is a  
242 powerful tool to assists decision makers.
