

EFFECT OF YEAR OF CALVING ON THE REPRODUCTIVE PERFORMANCE OF HOLSTEIN FRIESIAN COWS IN VOM PLATEAU STATE NIGERIA

ABSTRACT

The study was carried out to estimate the effect of year of calving on reproductive performance traits of Holstein Friesian cows that calved between 2006 – 2017. Five hundred and thirteen (513) calving records obtained from Integrated Dairy Farm Vom were collated for the study. Data was analyzed using the general linear models of SAS 2001 (version 8.0). Results revealed that the overall mean of Age at First Calving (AFC), Calving Interval (CI) and Days Open (DO) were 30.36 ± 0.23 months, 379.70 ± 13.34 days and 93.67 ± 9.74 days respectively. All the reproductive traits in the study have significant effect ($P < 0.05$) on year of birth of dam. The first, third, fourth and fifth calving interval has significant effect ($P < 0.05$) on year of birth while the second and sixth calving interval had no significant influence ($P > 0.05$) on year of birth. The observed reproductive performance of Holstein Friesian cattle under Vom condition was generally commendable. This may be attributed to improved management practices (such as high quality feed), maternal gene effect, accurate heat detection, timely insemination and adaptation of Holstein Friesian breed to the climatic condition of the study area (due to lower temperature).

INTRODUCTION

In the tropics, despite the large and diverse animal genetic resources, the productivity of many livestock especially the indigenous dairy cattle remains low. The increasing demand for milk and dairy products in Nigeria due to increasing population and improved standard of living may worsen if the bulk of multipurpose indigenous cows are with genetically low productive potentials (Alphonsus *et al.*, 2014). This is because milk production depends on the reproductive efficiency of the cow, with the best cows being those that calve at early age with little number of services per conception and with minimum calving interval; thereafter (Ngodigha *et al.*, 2009).

Kiwuwa *et al.* (1983) reported that the reproductive performance of the breeding female is probably the single most important factor that is a prerequisite for sustainable dairy production system and influencing the productivity. The size of the calf crop is all important for herd replacement and the production of milk depends heavily on the cow reproductive activity. The overall productivity and

36 adaptive efficiency of cattle depends largely on their reproductive performance in a
37 given environment (Wondossen et al., 2018). Any genetic improvement in dairy
38 cattle requires information reproductive performance in a given population
39 (Wondossen et al., 2018). Reproductive performance is biologically crucial
40 phenomenon and vital measurement for the profitability of many animal production
41 systems. Especially, the economics of dairy enterprise is based on an efficient
42 reproductive performance of dairy animals (Negussie et al., 1998). It is sometimes
43 used interchangeably with fertility (Massawe Heriel, 2011).

44 Dairy industry in Nigeria produces an estimated 450,000 tons of milk per
45 annum. This production has been found to be inadequate to satisfy the dairy
46 demands of Nigerians (FAO, 2010). This is because the genotype of the African
47 breeds of cattle can only produce an average milk of 1.27 litres per cow per day
48 during the wet season and less than 0.36 litres during the dry season (Yuan *et al.*,
49 2010), whereas their counterparts in the European and American produce an
50 average of 25 litres per day (Mallau-Aduli *et al.*, 2009). Consequently, protein
51 deficiencies become a common phenomenon in Nigeria, especially among the poor
52 segment of the society, which constituted majority of the populace (Saleh *et al.*,
53 2016)

54 According to Abdel Rahman and Aleman (2008) the Holstein-Friesian breed is known
55 for high milk productivity under the temperate climate. The high productivity of
56 Holstein-Friesian in temperate climates raises the question of how much of this
57 superiority in production is maintained when the animals are transferred to tropical
58 environment. Therefore, the objective of this study was to estimate the effect of
59 year of calving and environment factors on the reproductive performance of
60 Hosltein-Friesan cows in integrated Dairy Farm, Vom.

61 MATERIALS AND METHODS

62 Description of Study Area

63 The study was conducted in Integrated Dairy Farm (IDF) Ltd, a private
64 commercial dairy enterprise located at Vom Plateau State, Nigeria. Vom is situated
65 on the Jos Plateau 29km south West of Jos city. The town lies between latitudes

66 9°43 60" N and longitudes 8° 46' 60" E and has an altitude of 1222M above sea
67 level, with mean annual rainfall of 1400mm (55 inches). The area is defined by two
68 seasons; rainy season (May to October) and dry season (November to April). The
69 temperature ranges for 15–25°C, but from mid November to late January, night
70 temperature drops as low as 11°C (Encyclopaedia Britannica, 2017).

71

72 **Herd Description and Animal Management**

73 The Holstein Friesian cattle were maintained under intensive management
74 throughout the year. They were grazed on sown pasture in fenced paddocks
75 containing grasses and legumes in the morning and evening after which they were
76 turned to the stall (pen). In the dry season mixture of concentrates and silage/hay
77 were used to feed the cattle twice in a day. Steaming up was practiced at later stage
78 of pregnancy (2-3 months before calving). The cows were milked twice daily
79 (morning and evening) in the milking parlour using the milking machine. Calves were
80 weighed 24 hours of life (after birth) and weekly thereafter. The animals were
81 vaccinated against prevalent diseases and external parasites were also controlled
82 using spray. Routine deworming was also carried out.

83 **Mating System**

84 Artificial insemination was the main breeding method in the dairy farm.

85 **Experimental Design**

86 The experimental design used was the completely Randomized Design (CRD).

87 **Data Collection**

88 Five hundred and thirteen (513) calving records of Holstein Friesian cows were
89 collected from 2006 – 2017 for analysis. Data on Age at First Calving (AFC), Days
90 Open (DD) and Calving Interval (CI) were obtained as measures of reproductive
91 performance.

92

93 **Statistical Analysis**

94 Data obtained was subjected to analysis of Variance (ANOVA) using the General
95 linear models (GLM) procedure of Statistical Analysis System (SAS, 2001 version).
96 Where there is significant difference, means was separated using Duncan’s New
97 Multiple Range Test (DNMRT).

98 **RESULTS**

99 **Age at First Calving (AFC)**

100 The result showed that year of birth had significant ($P < 0.05$) effect on Age at First
101 Calving of Holstein Friesian cows at Integrated Dairy Farm Vom. The overall mena
102 for AFC was 30.36 ± 0.23 months. The result also indicated that high AFC (32.94
103 months) was recorded in 2011 and heifers born in 2013 had the lowest mean AFC
104 (26.94 months).

105 **Table 1: Least Square Means (LSM) for Effect of Year of Birth. On Age at**

2011	36	32.94 ± 0.67^a
2012	42	28.86 ± 0.69^c
2013	57	26.94 ± 0.42^d
2014	50	28.61 ± 0.52^c
Overall Mean		30.36 ± 0.23

108 **Note:** ^{abcd} LS mean with different superscript in the same column are significantly
109 different ($P < 0.05$); * = $P < 0.05$; N = Number of observation.

110 **Days Open (DO)**

111 The result showed that year of birth had significant ($P < 0.05$) effect on Days open of
112 Holstein Friesian cows in Integrated Dairy Farm Vom. The overall mean for DO was
113 93.67 ± 9.74 days. The result indicated highest level of DO in 2011 (118.10 ± 30.40)
114 days and lowest DO in 2013 (83.85 ± 7.30 days).

115 **Table 2: Least Square Means of Effect of Year of Birth. On Days open of**
116 **Holstein Friesian Cows at Integrated Dairy Farm Vom**

Year of Birth	N	Days Open (Days) LSM \pm SE

2011	27	118.10 ± 30.40^a
2012	26	90.62 ± 6.59^{ab}
2013	34	83.85 ± 7.30^b
2014	5	97.60 ± 15.20^{ab}
Overall Mean		93.67 ± 9.74

117
118 **Note:** ^{ab} LS Mean with different superscript in the same column are significantly
119 different ($P < 0.05$); * = $P < 0.05$; * $P < 0.05$; N = Number of observation.

120

121 **Calving Interval (CI)**

122 The result showed that year of birth had significant ($P < 0.05$) effect on calving
123 interval of Holstein Friesian cows in Integrated Dairy Farm, Vom. The overall mean
124 for Calving Interval (CI) was 379.70 ± 13.34 days. The highest calving interval was
125 in 2008 (453.20 ± 31.00 days) while the lowest was in 2014 (345.20 ± 35.90 days)
126 indicative of improved management.

143
144 **DISCUSSION**

145 Accurate estimation of reproductive performance of Holstein Friesian is very
146 important for improving the management practices and profitability of dairy farms
147 (Wondossen *et al.*, 2008).

148 ➤ AFC has a great economic importance in the efficiency of dairy cattle production
149 as it affects productive life of a cow (Wondossen *et al.*, 2018). The overall mean
150 in this study (30.36 months) was higher than the recommended AFC of 23-25
151 months for heifers to calve, but was similar to the work of Gwaza *et al.*(2007)
152 and Ajili *et al.*(2007) who reported AFC values of 309 and 29.28 months
153 respectively. It was however shorter than 39.2, 42.16, 33.27, 36.48, 33.73 and

154 39.4 months reported by Tadesse et al. (2010), Fekadu et al.(2011), Kollalpitaya
155 et al. (2012), Kebede (2015), Zelalem et al. (2015) and Wondossen et al.(2018)
156 respectively. The AFC in this study agrees with the average AFC in many tropical
157 countries and if indicated improve management practice in the farm such as
158 good nutrition.

159 In the present study, AFC was significantly ($P<0.05$) influenced by year of birth. The
160 AFC was found to be shorter in the latter years especially cows born in 2012, 2013
161 and 2014 (28.86, 26.94 and 28.61 months respectively) compared to the ones born
162 in previous or former years (2006 – 2011) with longer AFC. This could be attributed
163 to change in herd management in the latter years such as improved feeding, health
164 and reproductive health. Therefore, decreasing AFC implies a progressive
165 improvement in management practices of heifers and improved reproductive health.
166 This work agrees with earlier findings by Haile (2014) and Habfamtu et al. (2010)
167 who reported that changes in feeding management environmental conditions which
168 varied from year to year as well as differences between year in the quality and
169 quantity of forage available.

170 ➤ The overall mean for Days Open (DO) was 93.67 days. This falls within the
171 desired optimum value of 85 – 115 days and 75 – 90 days reported by Hammoud
172 et al. (2010) and Fernando et al. (2016) respectively required for improve herd
173 management. Days open is part of calving that can be reduced by improving
174 herd management. The value obtained in this study can be attributed to normal
175 calving to service period, regular oestrus and good management such as proper
176 feeding.

177 The study showed that year of birth had significant ($P<0.05$) effect on Days open.
178 This agrees with the finding of Haile (2014) who reported significant effect for years
179 of calving on Days open.

180 The value obtained in this study is shorter than 208, 179.9 and 156.44 days reported
181 by Haile (2014), Wondossen et al. (2018) and Fernando et al. (2016) respectively.
182 Long DO may affect the overall economic revenues of the dairy herd. Delayed
183 resumption of ovarian activity after calving and management factors such as

184 inadequate heat detection, decisions of breeding after parturition, nutrition and
185 diseases are some of the causes of higher length of DO.

186 ➤ The study showed that years of birth significantly ($P < 0.05$) affected the calving
187 interval. This agrees with the work of Haile (2014) and Tadesse *et al.* (2010) who
188 reported significant effect of CI on year of birth for Holstein Friesian cows.

189 The overall mean calving interval of 379.70 days (12.5 months) in this study falls
190 under the optimum recommended level of 12-13 months as reported by Hammoud
191 *et al.* (2010) and Fernando *et al.* (2016) for a well managed farm. This also agrees
192 with previous reports of Hunduma (2012), Ogundipe and Adeoye (2013) and Sena *et al.*
193 *et al.* (2014) who reported 12.4 months, 374 days and 13.06 months respectively. The
194 value may be as a result of normal calving to service period, environmental factors
195 and good reproductive managements such as accurate heat detection, timely
196 insemination and efficiency of AI technicians and also adequate and high quality
197 feed supply. Many researchers in the tropics reported higher level of CI such 436
198 days, 462.87 days, 14.64 months, 431.41 days and 469.2 days reported by
199 Ogundipe and Adeoye (2013), Kebede (2015), Zelalem *et al.* (2015), Fernando *et al.*
200 (2016) and Wondossen *et al.* (2018) respectively.

201 The study also showed significant decline of CI as the calving year advanced from
202 2008 (453.20 days) to 2014 (345.20 days). The marked decrease observed shows
203 an improvement in the levels of management such as supplementation of lactating
204 cows, better oestrus detection, better ratification insemination services and improved
205 regular follow up of breeding cows.

206 Table 4 in the current study showed year of birth had significant ($P < 0.05$) effect on
207 the first, third, fourth and fifth calving interval but showed non significant ($P > 0.05$)
208 effect on the second and sixth calving interval. The variation in all the calving
209 intervals from year to year indicated a progressive improvement in management,
210 maternal gene effect, accurate heat detection and timely insemination.

211

212

213 **CONCLUSION**

214 The reproductive performance assessed in the present study showed that year of
215 calving had significant ($P < 0.05$) affected virtually all the factors (Age at first calving,
216 days open and calving interval). The ultimate goal of a breeder is to lower the age at
217 first calving, Days open and calving interval. The reproductive performance of the
218 Holstein-Friesian cows in Vom Integrated Dairy Farm was commendable when
219 compared to other tropical conditions.

220 Based on the above conclusion, the following recommendations were forwarded.

- 221 ❖ Further studies should be carried out on the effect of season and parity on
222 reproductive performance in the same farm.
- 223 ❖ Better management practices such as improved nutrition and use of new
224 reproductive technology can help improve the reproductive performance of
225 the HF cows in Vom to perform similar to the temperate ones.
- 226 ❖ Setting up of more farms in Vom area by private individuals, investors, multi-
227 nationals and Federal Government of Nigerian can help reduce the incessant
228 herders/farmers crisis that always led to loss of lives and properties in Nigeria.
229 It will further increase protein (milk) intake of Nigerians.
- 230 ❖ Climatic records such as temperature, relative humidity and rainfall should be
231 kept in the farm to distinguish the variations across the years.
