**A comparative Evaluation Of Selected Medicinal Plants on Male fertility indices ( reproductive hormones and sperm profile) of albino wistar rats. An Animal Case study**

3

4

5 **Abstract:** The study aims to investigate the effects of the medicinal plants{seeds} on the  
6 reproductive hormones and sperm profile of male albino rats to ascertain their possible usefulness  
7 as fertility agent. Walnuts [Tetracarpidium conophorum] ,Sesame (Sesamine indicum),and Velvet  
8 bean(Mucuna pruriens) seeds were obtained and taken to the Department of plant Science and  
9 Biotechnology, University Of Nigeria , Nsukka(UNN). The seeds were milled into fine powder. One  
10 hundred and ten sexually matured albino rats of about twelve weeks weighing 130-180g were  
11 divided into eleven groups (1-11) using completely randomized design. There were two different  
12 control groups and rats in group 1 served as the Control 1 and were fed with normal commercial  
13 feed. Rats in group 2 were administered with a drug (Ketoconazole) to induce infertility. The  
14 **Infertility Induced groups** were treated with low dose (groups 3-5), medium dose (groups 6-8) and  
15 high dose (9-11) for the period of nine (9) weeks. At the end testes and Epididymides were  
16 surgically removed and weighed. Blood sample analysis revealed that the concentration of sex  
17 hormones measured in the male rats fed with medium plants (seeds) showed that the testosterone  
18 concentration significantly increased ( $p < 0.05$ ) in animal control group 1(normal rats) Therefore,  
19 these medicinal plants walnut seeds showed significant increase in their testosterone concentration,  
20 luteinizing hormone (LH) and follicle stimulating hormone (FSH) which significantly enhanced the  
21 production of reproductive hormones which enriched the fertility status of these animals.

22 **Keywords:** albino rats, medicinal plants, reproductive hormones, sperm profile, **testis histology**

24

## 1. INTRODUCTION

25

26 Medicinal plants are plants that contain properties or compounds that can be used for  
27 therapeutic purposes or those that synthesize metabolites to produce useful drugs (WHO 2008). The  
28 pharmacological evaluation of substances from plants is an established method for the identification  
29 of lead compounds which can lead to the development of novel and safe medicinal agents (Golla et  
30 al., 2011). Historically, all medicinal preparations were derived from plants whether in the simple  
31 form of raw plants materials or in the refined form of crude extracts, mixtures (Krishnaraju et al.,  
32 2005). The rich knowledge base of countries like India and China in medicinal plants and health care  
33 has led to the keen interest by pharmaceutical companies to use this knowledge as a resource for  
34 research and development programs in the pursuit of discovering novel drugs (Mukherjee & Wahile,  
35 2006). Nigeria is also among countries blessed with a wide range of such medicinal plants which  
36 have not been thoroughly evaluated for their bioactive/ therapeutic agents. Primary among this list  
37 of properties is their antioxidants, antibacterial and antifungal activities (Ajaiyeoba and Fadara ,  
38 2006). However, some of such botanicals are Tetracarpidium conophorum, Sesame indicum L and  
39 Mucuna pruriens. These plants have antimicrobial activity which may cure some sexually transmitted  
40 infections that could be responsible for male fertility (Ajaiyeoba and Fadara 2006). Researchers have  
also shown that these plants possess some essential antioxidants and Vitamins capable of fighting

41 off reactive oxygen species, thereby assisting seminal plasma exhibiting a strong capacity to maintain  
42 a relatively neutral and protective environment for sperm function (Orth et al; 1993; Foresta et al,  
43 2004). There are reports that abnormalities in sex hormone biosynthesis may impair  
44 spermatogenesis. The failure of the pituitary to maintain proportionate levels of FSH,LH and PRL  
45 may lead to disruption of testicular function, leading to infertility (Dashistani and Dayem, 2007).The  
46 seeds have also been found to contain major essential fatty acids (Omega-3DHA and Omega-6)  
47 which include oleil, linolenic and linolenic acids (Zwarts et al; 1999; savage, 2001; Ozkan and  
48 koyuncu, 2005, Ahmed et al, 2008,). Essential fatty acids act as hormone regulators and its  
49 purported that sperm contain high concentrations of Omeg-3's.

50 The main purpose of the research work therefore is to investigate the effects of the  
51 medicinal plants (seeds) on the reproductive hormones and sperm profile of male albino rats in  
52 order to ascertain possible usefulness as a fertility agent.

53

## 2. MATERIALS AND METHODS

54 The seeds of walnut (*Tetracarpidium conophorum* ), Sesame (*Sesamium indicum*), and  
55 Velvet bean (*Mucuna pruriens*) were procured and sent to the department of plant science and  
56 Biotechnology, University of Nigeria (UNN) for identification and authentication. **The seeds were**  
57 **cut into pieces and dried for fort-eight hours and ground** into fine powder using electric blender.

58 **Experimental Animals and Administration of Seeds.** Ninety sexually matured male albino rats of  
59 about twelve weeks weighing between 130-180g were used for this experiment. They were kept in a  
60 well ventilated conventional cage (temperatures: **28-31°C**, photoperiod: 12hours of natural light and  
61 12hours of darkness; humidity: 50-55%) and acclimatized for two weeks with tap water before  
62 commencement of treatments. The rats were divided into eleven groups (1-11) using completely  
63 randomized design with six male and four female rats in each group. There were two different  
64 control groups in this research. Rats in group (1) served as the control 1 and were fed with normal  
65 commercial feed only **and** rats in group (2) served as control ii and were administered with a drug  
66 (ketoconazole) reported to induce infertility to rats, including dog and primate (Vawda and Davies,  
67 1986; Donald et al , 1990). To evaluate further the potentials of the seeds, the infected groups were  
68 treated with low dose (groups 3-5), medium dose (groups 6-8) and high dose (groups 9-11) using  
69 dietary inclusion for the period of nine weeks.

### 70 **Preparation of Serum and Semen for fertility Examination.**

71 At the end of the treatment regime, the rats were anaesthetized using diethyl ether. The testes and  
72 Epididymides were surgically removed and weighed. Blood samples, 15ml per each rat were  
73 collected through cardiac puncture into sterile tubes for hormonal analysis.

### 74 **Hormone Assay**

75 The blood samples collected were centrifuged at 2500rpm for 5minutes using a centrifuge at 10-  
76 20oc to obtain the serum samples which were analyzed for testosterone, follicle stimulating  
77 hormone (FSH), luteinizing hormone (LH) and estradiol hormone level using enzyme linked  
78 immunoassay (ELISA) technique (Ekaluo et al; 2010)

79

80 **Semen Analysis**

81 (a) Determination of Epididymides and weight.

82 These Epididymides and testes were dissected out and excess blood damped into cotton wool and  
83 placed in a clean weighing balance to record the weight.

84 (b) Evaluation of sperm motility

85 Semen samples from the different treatment groups were dropped on a glass slide and viewed  
86 under the microscope. A minimum of five microscopic fields were assessed to evaluate sperm  
87 motility and were analyzed for progressive motile sperm (PMS), non-progressive motile sperm  
88 (NPMS) and non-motile sperm (NMS) distinguished by the movement of the sperm cells (World  
89 Health Organization, 1992)

90 (c) Estimation of mean sperm count

91 The mean sperm count was carried out according to the method of (Ekaluo et al; 2009)

92 (d) Estimation of sperm viability

93 Sperm viability was estimated using the improved one step eosin-nigrosin staining technique. A  
94 fraction of each suspension of the sperm samples were mixed with equal volume of eosin-nigrosin  
95 stain and air dried smears were prepared on glass slides for each samples as described by Bjorn dahl  
96 et al, (2003).

97 (e) Estimation of Semen PH

98 The PH of semen was measured using a specially treated calibrated paper blot that changes colour  
99 according to the PH of the semen that it is exposed to (Comhaire and Vermeulen, 1995)

100 (f) Sperm head abnormalities

101 A fraction of each of the sperm suspension was examined by placing the solution (10:1) for 30  
102 minutes on a glass slide. The slide was examined for percentage abnormalities in every 200  
103 spermatozoa on each slide and fine air dried smear prepared on glass slide for each sample  
104 according to (Ekaluo et al; 2005).

105

106

**3. RESULTS AND DISCUSSIONS**

107 Table 1 shows the results of the impacts of medicinal plants on the sperm quality of the albino rats.  
108 The result revealed no significant increase ( $p>0.5$ ) in the sperm motility between the animal groups  
109 1,6,7,9 and 11 and these groups showed a significant increase ( $p<0.5$ ) when compared with that of  
110 other experimental groups. The sperm motility was significantly lower ( $p<0.05$ ) in the animal groups  
111 2,3,4,5,8 and 10. The result in respect of sperm count showed a significant increase ( $p<0.05$ ) in the  
112 group 1 compared across all the induced animal groups 2-11. However, there was no observed  
113 significant difference ( $p>0.05$ ) between the group 2 and the animal groups treated with the  
114 medicinal plant samples. Sperm viability was observed to be significantly high ( $p<0.05$ ) in the groups

115 1,5,6,8,10,and 11 compared to other treated groups. Also, there were no significant difference  
 116 ( $p>0.05$ ) in the sperm viability between the animals in groups 2,3,and these groups showed  
 117 significant decrease( $p<0.05$ ) in the sperm PH of the rats in all the groups. Meanwhile, Testes and  
 118 Epididymides weight of the group 6 was significantly higher( $p<0.05$ ) than that of groups 1,4,5,and  
 119 8.However,the results revealed no significant increase ( $p>0.05$ ) of the Testes and Epididymides  
 120 weight between the groups 2,3,7,9,10 and11.

121 All values are expressed as Mean +Standard Deviation (SD).Mean values with the same letters as  
 122 superscripts along the column are considered non-significant difference ( $p>0.05$ ) while mean values  
 123 with different letters as superscripts are considered significant( $p<0.05$ ).

**(Tetracarpidium conophorum, Sesame indicum L, and Mucuna pruriens) seeds.**

130 The results of the concentration of sex hormones measured in the male rats fed with medicinal  
131 plants (seeds) shown in the table 2. From the result, the testosterone concentration showed  
132 significant increase ( $p < 0.05$ ) in animal control group 1 (normal rats) while the concentration of the  
133 hormone in group 2 (ketoconazole induced animals with no treatment) significantly decreased  
134 ( $p < 0.05$ ) when compared across the treated groups 3-10 (Induced rats fed with 4g, 8g and 12g/kg  
135 between day of the test samples). Group 11 (Induced rats fed with 12g/kg between day of walnut  
136 sample) also revealed a significant increase ( $p < 0.05$ ) when compared with the rest of the treatment  
137 groups 3-10. The result of the present study also revealed a significant increase ( $p < 0.05$ ) in the  
138 concentration of FSH in the control group 1 (normal rats) when compared with that of groups 2-11  
139 (animals fed with 4, 8 and 12kg/g test samples). However, there was also an observed significant  
140 increase ( $p < 0.05$ ) in the concentration of Luteinizing hormone (LH) in the group 1 compared to that  
141 of groups 2-10 but the result revealed no significant increase ( $p > 0.05$ ) when compared group 1  
142 (normal rats) and that of group 11 (animals fed with 12kg/g walnut sample). Group 5 (animals fed  
143 with 4kg/g walnut sample) and 6 (animals fed with 8kg/g velvet bean sample) showed significant  
144 decrease ( $p < 0.05$ ) when compared across other treatment groups. Moreover, the results of the  
145 estradiol in table 2 indicate a significant decrease ( $p < 0.05$ ) in group 1 (normal rats) compared to that  
146 group 2 (ketoconazole induced animals with no treatment) and that of the treatment groups 3-10  
147 (animals fed with 4, 8 and 12kg/g test samples) but no significant difference ( $p > 0.05$ ) was observed  
148 when compared with that of group 11 (animals fed with 12kg/g walnut sample).

153

154

155

#### 4. CONCLUSION

156

The concentration of sex hormones measured in the male rat fed with medicinal plants (seeds) showed that the testosterone concentration significantly increased ( $p < 0.05$ ). It was also deduced that these medicinal plants including Walnut seeds significantly increased their Luteinizing hormone (LH) and Follicle Stimulating Hormone (FSH). This eventually enhanced the production of the reproductive hormones which enriched the fertility status of these animals.
