**Original Research Article**

**A Comparative Analysis of Selected Fisher Linear Discriminant Based Algorithms in Human Faces**

---

**ABSTRACT**

One of the most reliable biometrics when issues of access control and security is been considered is face recognition. An integral part of a face recognition system is the feature extraction stage, which becomes a critical problem where is a need to obtain the best feature with minimum classification error and low running time. Many of the existing face recognition systems have adopted different linear discriminant-based algorithms independently for feature extraction in which excellent performance were achieved, but identifying the best most suitable of these variants of linear discriminant-based algorithms for face recognition systems remains a subject open for research. Therefore, this paper carried out a comparative analysis of the performance of the basic Linear Discriminant Algorithm (LDA) and two of its variants which are Kernel Linear Discriminant Analysis (KLDA) and Multiclass Linear Discriminant Analysis (MLDA) in face recognition application for access control.

Three Hundred and forty (340) face images were locally acquired with default size of 1200 x 1200. Two hundred and forty (240) images were used for training while the remaining hundred (100) images were used for testing purpose. The image enhancement involves converting into grayscale and normalizing the acquired images using histogram equalization method. Feature extraction and dimension reduction of the images were done using each of LDA, KLDA and MLDA algorithms individually. The extracted feature subsets of the images from each of LDA, KLDA and MLDA algorithm were individually classified using Euclidian distance. This technique was implemented using Matrix Laboratory (R2015a). The performance of LDA, KLDA and MLDA was evaluated and compared at 200 x 200 pixel resolution and 0.57 threshold value using recognition accuracy, sensitivity, specificity, false positive rate, training time and recognition time.

The evaluation result shows that the LDA algorithm yielded recognition accuracy, sensitivity, specificity, false positive rate, training time and recognition time of 93.00%, 92.86%, 93.33%, 6.67%, 1311.76 seconds and 67.98 seconds respectively. Also, KLDA recorded recognition accuracy, sensitivity, specificity, false positive rate, training time and recognition time of 95.00%, 95.71%, 93.33%, 6.67%, 1393.24 seconds and 63.67 seconds respectively. Furthermore, MLDA algorithm yielded recognition accuracy, sensitivity, specificity, false positive rate, training time and recognition time of 97.00%, 97.14%, 96.67%, 3.33%, 1191.55 seconds and 58.65 seconds respectively. The t-test measured between the accuracies of MLDA algorithm and KLDA reveals that MLDA algorithm was statistically significant at

$P < 0.05$ ;  $P = 0.014$  and  $\mu = 1.50$ . Also, the t-test measured between the accuracies of MLDA algorithm and LDA reveals that MLDA algorithm was statistically significant at  $P < 0.01$ ;  $P = 0.001$  and  $\mu = 3.75$ .

## 1. INTRODUCTION

With continuous increase in world population, identification and authentication of individuals is becoming more significantly important. Hence, the need for highly accurate, secured and practical identification and authentication systems. Over the years, many traditional identification and authentication systems such as usernames, passwords, keys, personal identification number (PIN), identification (ID) cards, hardware token- based systems have been use for access control, but each of them has its own attendant problems. Generally, they are not reliable and secure in many of the security zones. Thus, there is an increasing need for an automatic and reliable identification and authentication systems. Biometric identification has proven to be more reliable means of verifying the human identity [27]. Biometrics is the science of establishing human identity by using physical or behavioral traits such as face, fingerprints, palm prints, iris, hand geometry and voice [28]. The work focuses on face recognition as a form of biometric identification and authentication technique.

Face recognition is a technology which recognizes human by his/her face image. Face recognition has attracted much attention and is still attracting the interest of many researchers in the area of pattern recognition, machine learning, and computer vision because of its immense application potentials [17]. Generally, facial recognition involves four major stages. These stages include image acquisition, image pre-processing, feature extraction and image classification. Of these four major stages, feature extraction is the most essential. Basically, it consists of extracting the most relevant features of an image and assigning it into a label [19]. Extracting features from face images for detection and recognition purpose is a central issue for face recognition systems [5]. Although feature extraction methods provide researchers with the main features that are associated with the face image sufficient enough to make good recognition, the feature set produced by these methods have very large dimension [4]. Hence, the need for dimensionality reduction. Dimensionality reduction plays crucial role in the face recognition problem. It is generally applied for improving robustness and reducing computational complexity of the face recognition problem. Out of all approaches available at hand, those based on appearance is considered to be most favourable. Therefore, methods like Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA) are used for dimensionality reduction and hence can provide efficient matching of features of faces for recognition purposes [30].

Furthermore, extracting proper features is crucial for satisfactory design of any pattern classifier, and how to develop a general procedure for effective feature extraction remains an interesting and challenging problem [14]. Traditionally, PCA has been the standard approach to reduce the high-dimensional original pattern vector space into low-dimensional feature vector space. Comparative studies between Fisher Linear Discriminant Analysis (FLDA) and Principal Component Analysis (PCA) on the face recognition problem were reported independently by [6] and [12], in which FLDA out performed PCA significantly. These successful applications of FLDA have drawn a lot of attention on this subject and the ensuing years have witnessed a burst of research activities on various issues relating to applying subspace methods such as PCA and FLDA to pattern recognition problems, with the latest development being an attempt to unify all these subspace methods under the same framework [18]. LDA provides fast feature extraction and classification due to its discriminative power and computational simplicity. Variants of LDA include LDA, Kernel-LDA

66 (KLDA), Incremental LDA (ILDA) and Multiclass LDA (MLDA) [34]. They have been widely  
67 applied in many applications of pattern recognition, computer vision, face recognition, text-  
68 image combination multimedia retrieval, speech and music classification, outliers detection,  
69 generalized image and video classification and so on [9].  
70

71 This paper carried out a comparative assessment of the performance of LDA, and two of its  
72 variants, that is KLDA and MLDA in face recognition application. The face recognition  
73 system comprises of modules which involve face image acquisition, image preprocessing,  
74 feature extraction and feature classification for recognition. African face dataset from Ladoke  
75 Akintola University of Technology, Ogbomosho (LAUTECH) was used. The LDA techniques  
76 were used independently for feature extraction and the feature classification in all cases was  
77 achieved using Euclidean distance. The best among the three LDA techniques in face  
78 recognition was ascertained based on their performance. The rest of the paper is organized  
79 into the following: Section two presents review of relevant literatures to this research;  
80 Section three details the research methodologies employed in the comparative analysis;  
81 Section four present the results and Sections five summarized and concludes the paper.  
82

## 83 **2. LITERATURE REVIEW**

### 84 **2.1 Face Recognition**

85 Face recognition is one of the most important applications of biometrics based authentication  
86 system in the last few decades. Face recognition is a type of recognition task pattern, where  
87 a face is categorized as either known or unknown after comparing it with the images of a  
88 known person stored in the database. Over the years, face recognition has found  
89 applications in security, criminal justice systems, image database investigation, surveillance,  
90 smart card applications, video indexing, human computer interaction, multimedia  
91 environment with adaptive human computer interface to mention, but a few.  
92

93 Face recognition is a challenge, given the certain variability in information because of  
94 random variation across different people, including systematic variations from various factors  
95 such as lightening conditions, pose and so on [15]. The human face is an extremely  
96 complex and dynamic structure with characteristics that can significantly and quickly change  
97 in time. Face recognition involves a range of activities from various aspects of human life.  
98 Humans can recognize faces, but too many faces sometimes being hard to memorized,  
99 machine learning is now being improved to do this task. Researchers attempt to understand  
100 the architecture of the human face when building or developing face recognition systems.  
101 Atalay (1996) presented a face recognition system that heavily carries the characteristics of  
102 a typical pattern recognition system. The system was summarized in modules as follows  
103 [26]:  
104

- 105 i. Acquisition module is the entry point of the face recognition process. It is the module  
106 in which the face image under consideration is presented to the system. An  
107 acquisition module can request a face image from several different environments  
108 such as well-illuminated environment.
- 109 ii. Pre-processing module by means of early vision techniques, face images are  
110 enhanced by using histogram equalization method and if desired, they are enhanced  
111 to improve the recognition performance of the system.
- 112 iii. Feature extraction module takes place after performing some pre-processing (if  
113 necessary), the normalized face image is presented to the feature extraction module  
114 in order to find the key features that are going to be used for classification.
- 115 iv. Classification module are used, with the help of a pattern classifier, extracted  
116 features of the face image is compared with the ones stored in a face library (or face  
117 database). After doing this comparison, face image is classified as either known or  
118 unknown. Training sets are used during the "learning phase" of the face recognition

119 process. The feature extractions and the classification modules adjust their  
120 parameters in order to achieve optimum recognition performance by making use of  
121 training sets. Face library or face database is a repository of face images which after  
122 some face images are being classified as "unknown", face images can be added to  
123 a library (or to a database) with their feature vectors for later comparisons. The  
124 classification module makes direct use of the face library [26].  
125

## 126 **2.2 Feature Extraction Techniques**

127 Feature extraction is a very important field of image processing and face recognition.  
128 Fundamental component of characters is called features. The basic task of feature extraction  
129 and selection is to find out a group of the most effective features for classification; that is,  
130 compressing from high-dimensional feature space to low-dimensional feature space, so as  
131 to design classifier effectively [10]. Feature extraction process can be defined as the  
132 procedure of extracting relevant information from a face image. This information must be  
133 valuable to the later step of identifying the subject with an acceptable error rate. The feature  
134 extraction process must be efficient in terms of computing time and memory usage. The  
135 output should also be optimized for the classification step. Feature extraction involves  
136 several steps - dimensionality reduction, feature extraction and feature selection. These  
137 steps may overlap, and dimensionality reduction could be seen as a consequence of the  
138 feature extraction and selection algorithms. Both steps could also be defined as cases of  
139 dimensionality reduction [13].  
140

141 Dimensionality reduction is an essential task in any pattern recognition system. The  
142 performance of a classifier depends on the amount of sample images, number of features  
143 and classifier complexity. One could think that the false positive ratio of a classifier does not  
144 increase as the number of features increases. However, added features may degrade the  
145 performance of a classification algorithm. This may happen when the number of training  
146 samples grow exponentially with underlying dimensionality. This problem is called "curse of  
147 dimensionality" or "peaking phenomenon".  
148

149 A generally accepted method of avoiding this phenomenon is to use at least ten times as  
150 many training samples per class as the number of features. This requirement should be  
151 satisfied when building a classifier. The more complex the classifier, the larger should be the  
152 mentioned ratio [14]. This "curse" is one of the reasons why it's important to keep the  
153 number of features as small as possible. The other main reason is the speed. The classifier  
154 will be faster and will use less memory. Moreover, a large set of features can result in a false  
155 positive when these features are redundant. Ultimately, the number of features must be  
156 carefully chosen. Too less or redundant features can lead to a loss of accuracy of the  
157 recognition system. There are two predominant approaches to the face recognition problem:  
158 geometric (feature based) and photometric (view based). As researcher interest in face  
159 recognition continued, many different algorithms were developed, such as Discrete Cosine  
160 Transform (DCT), Principal Components Analysis (PCA), Fisher Linear Discriminant  
161 Analysis (FLDA), and Elastic Bunch Graph Matching (EBGM).  
162

## 163 **2.3 Linear Discriminant Analysis (LDA)**

164 Originally developed in 1936 by R.A. Fisher, discriminant analysis is a classic method of  
165 classification that has stood the test of time. Discriminant analysis often produces models  
166 whose accuracy approaches (and occasionally exceeds) more complex modern methods.  
167 Discriminant analysis can be used for classification (that is with a categorical target variable),  
168 not for regression. The target variable may have two or more categories. It is also known as  
169 Fisher Discriminant Analysis (FDA) [21]. Dimensionality reduction is fundamentally important  
170 for analyzing high-dimensional data, and has received sufficient attention in the field of  
171 artificial intelligence [23]. The goal of dimensionality reduction is to embed the data into a

172 low-dimensional subspace, while retaining the desired discriminant information. The pseudo  
 173 code for LDA is depicted below:

174 The description of Fisher Linear Discriminant Analysis procedure is given below:

175 Given the data matrix  $X = [x_1, x_2, \dots, x_n]$ ,  $x_j \in \mathbb{R}^{d+1}$  with  $C$  classes, the purpose of  
 176 LDA is to learn a linear transformation matrix  $W \in \mathbb{R}^{d+m}$  ( $m \ll d$ ) to map the  $d$ -  
 177 dimensional data  $x_j$  to a  $m$ -dimensional vector:

$$178 \quad y_j = W^T x_j \quad (2.1)$$

179 FLDA supposes that an optimal transformation should push the data points from different  
 180 classes far away from each other while pulling those within the same class close to each  
 181 other. So the objective of FLDA can be written as

$$\max_W \frac{\sum_{i=1}^C n_i \|W^T(\mu^i - \mu)\|_2^2}{\sum_{i=1}^C \sum_{j=1}^{n_i} \|W^T(x_j^i - \mu^i)\|_2^2} \quad (2.2)$$

182 where  $n_i$  is the number of samples in class  $i$ ,  $\mu^i$  is the mean of the samples in class  $i$ ,  $\mu$  is the  
 183 mean of all the samples, and  $x_j^i$  is the  $j$ -th sample in class  $i$ . Denote the between-class  
 184 scatter matrix  $S_b$  and the within-class scatter matrix  $S_w$  as in equation (2.3) and (2.4)  
 185

$$186 \quad S_b = \sum_{i=1}^C n_i (\mu^i - \mu)(\mu^i - \mu)^T \quad (2.3)$$

$$187 \quad S_w = \sum_{i=1}^C \sum_{j=1}^{n_i} (x_j^i - \mu^i)(x_j^i - \mu^i)^T \quad (2.4)$$

188 then the problem can be rewritten into a concise form:  
 189

$$\max_W \frac{\text{tr}(W^T S_b W)}{\text{tr}(W^T S_w W)} \quad (2.5)$$

190 Where  $\text{tr}()$  indicates the trace operator. Due to the complexity to solve the above trace ratio  
 191 problem, many researchers transform it into a ratio trace form,  
 192

$$\max_W \text{tr} \left( \frac{W^T S_b W}{W^T S_w W} \right) \quad (2.6)$$

193  
 194

## 195 **2.4 Kernel Linear Discriminant Analysis (KLDA)**

196 KLDA is a generalization of Fisher Linear Discriminant Analysis (FLDA), a statistical method  
 197 to find linear combinations of features (that is variables in a data set, or points in a trace) that  
 198 characterize class separations. In particular, it outputs projection directions that maximize  
 199 the ratio of between-group to within group scatter, so that 'interesting' variation may be  
 200 concentrated into a reduced dimension space for further analysis. KLDA has been promoted  
 201 as one of a number of methods to extract sensitive data dependent features from side-  
 202 channel traces for some years [31]. However, because it only finds linear combinations, it is  
 203 unable to locate the types of joint data dependencies exhibited by traces which have been  
 204 protected by software masking. By contrast, the 'kernel trick' employed by KLDA allows to  
 205 implicitly map the data into a higher dimensional feature space within which to perform the  
 206 discriminant analysis, thereby extracting non-linear combinations of the sort that do yield  
 207 sensitive information on further analysis [31]  
 208 .

209 Discriminant Analysis with Kernels LDA can be used to find optimal linear mappings of high  
 210 dimensional data but is not applicable when the relevant information is known to be  
 211 contained in non-linear combinations of points, as is the case for side-channel leakages of  
 212 masked implementations. To extend FLDA to the non-linear case, we consider the problem  
 213 in a feature space  $F$  induced by some mapping function (this mapping process is implicit as  
 214 will be seen in the following subsection),  $\Phi: R^n \rightarrow \mathcal{F}$ . KLDA is used to find nonlinear  
 215 directions by first mapping the data non-linearly by  $\Phi$  into some feature space  $F$  within which  
 216 to compute linear discriminants, thus implicitly yielding a non-linear discriminant in the input  
 217 space [20]. To find such a discriminant, equation 2.7 is used:  
 218

$$219 \quad J(\omega') = \frac{W^T S_B^\Phi \omega'}{W^T S_W^\Phi \omega'} \quad (2.7)$$

220 Where  $\omega' \in \mathcal{F}$  and  $S_B^\Phi$  and  $S_W^\Phi$  are the corresponding matrices in  $F$ .

$$221 \quad S_B^\Phi = \sum_{m \in M} n_m \left( \frac{1}{n_m} \sum_{m_i=m} P_i^\Phi - \frac{1}{N} \sum_{i=1}^N P_i^\Phi \right)^T \left( \frac{1}{n_m} \sum_{m_i=m} P_i^\Phi - \frac{1}{N} \sum_{i=1}^N P_i^\Phi \right) \quad (2.8)$$

222

$$223 \quad S_W^\Phi = \sum_{m \in M} \sum_{m_i=m} \left( P_i^\Phi - \frac{1}{n_m} \sum_{m_i=m} P_i^\Phi \right)^T \left( P_i^\Phi - \frac{1}{n_m} \sum_{m_i=m} P_i^\Phi \right) \quad (2.9)$$

224

225 where  $P_i^\Phi$  is  $\Phi(P_i)$  projection of  $P_i$  on  $F$  by  $\Phi$ . For a properly chosen  $\Phi$  an inner product  $\langle \cdot, \cdot \rangle$   
 226  $>$  can be defined on  $F$ , which makes for a so-called 'reproducing kernel Hilbert space',  
 227

$$228 \quad K(x, y) = \langle \Phi(x), \Phi(y) \rangle \quad (2.10)$$

229

230 where  $K$  is known as the kernel function. Widely-used kernel functions include the Gaussian  
 231 kernel  $K(x, y) = \exp(-\|x - y\|^{2/c})$  ( $\|\cdot\|$  is the 2-norm), and the polynomial kernel  $K(x, y) =$   
 232  $(x \cdot y)^{d'}$ , for positive constants  $c$  and  $d'$  satisfying Mercer's condition [25], as defined in [29].  
 233

## 234 2.5 Multiclass Linear Discriminant Analysis (MLDA)

235 If the number of classes is more than two, then a natural extension of Fisher Linear  
 236 discriminant exists using multiple discriminant analysis [16]. As in two-class case, the  
 237 projection is from high dimensional space to a low dimensional space and the transformation  
 238 suggested still maximizes the ratio of intra-class scatter to the inter-class scatter. But unlike  
 239 the two-class case, the maximization should be done among several competing classes.  
 240 Suppose that now there are  $n$  classes. The intra-class matrix is calculated as:

$$241 \quad \Sigma_w = S_1 + \dots + S_n = \sum_{i=1}^n \sum_{x \in C_i} (x - \bar{x}_i)(x - \bar{x}_i)' \quad (2.11)$$

242

243 The inter-class scatter matrix slightly differs in computation and is given by  $\Sigma_b =$   
 244  $\sum_{i=1}^n m_i (\bar{x}_i - \bar{x})(\bar{x}_i - \bar{x})'$  (2.12)

245

246 Where  $m_i$  is the number of training samples for each class,  $\bar{x}_i$  is the mean for each class  
 247 and  $\bar{x}$  is total mean vector given by  $\bar{x} = \frac{1}{m} \sum_{i=1}^n m_i \bar{x}_i$ . After obtaining  $\Sigma_b$  and  $\Sigma_w$ , the linear  
 248 transformation  $\Phi$ . It can be shown that the transformation  $\Phi$  can be obtained by solving the  
 249 generalized eigenvalue problem:

$$250 \quad \Sigma_b \Phi = \lambda \Sigma_w \Phi \quad (2.13)$$

251

252 It is easy to prove that the upper bounds of the rank of  $\Sigma_b$  and  $\Sigma_w$  are respectively  $m-n$  and  
 253  $n-1$ . Multiple discriminant analysis provides an elegant way for classification using  
 254 discriminant features. If classification is required, instead of dimension reduction, there are a  
 255 number of alternative techniques available. For instance, the classes may be partitioned,

256 and a standard Fisher discriminant or LDA used to classify each partition. A common  
257 example of this is "one against the rest" where the points from one class are put in one  
258 group, and everything else in the other, and then LDA applied. This will result in  $C$   
259 classifiers, whose results are combined. Another common method is pair-wise classification,  
260 where a new classifier is created for each pair of classes (giving  $C(C - 1)/2$  classifiers in  
261 total), with the individual classifiers combined to produce a final classification.  
262

## 263 **2.6 Related Works**

264  
265 [8] proposed a technique that involved using FLDA for classification. The approach was  
266 termed Clustering based Discriminate Analysis (CDA) and achieved a recognition accuracy  
267 of 93% for three classes of expression. The conventional linear approach like LDA and PCA  
268 are straightforward and proficient on the grounds that they are linear. Notwithstanding, these  
269 are not appropriate for representing powerfully changing facial expressions in light of the fact  
270 that the changing expressions are characteristically non-linear.  
271

272 [11] present a novel face recognition system that uses two-class linear discriminant analysis  
273 for classification. In this approach a single  $M$ -class linear discriminant classifier was divided  
274 into  $M$  two-class linear discriminant classifiers. This formulation provides many advantages  
275 like more discrimination between classes, simpler calculation of projection vectors and  
276 easier update of the database with new individuals. The proposed algorithm was tested on  
277 the CMU PIE and Yale face databases. Two-class LDA performs slightly better than the  
278 multi-class LDA, where there is only 2.22%, 10.29%, performance difference between the  
279 best classification scores of these two algorithms for Yale and CMU respectively. Significant  
280 performance improvements were observed, especially when the number of individuals to be  
281 classified increases.  
282

283 [22] proposed an optimised fisher discriminant analysis for recognition of faces having black  
284 features. About 460 faces samples from 46 black African individuals (with and without tribal  
285 marks) were acquired. In the experiment, different sizes of gray scale images were used for  
286 recognition and performance accuracy of between 88 and 99% were obtained. Also, taken  
287 into consideration was the rate of identifying an image using the same number of images to  
288 test the face recognition system. The optimized fisher discriminant analysis was found to be  
289 efficient.  
290

291 [7] proposed a face recognition system by Linear Discriminant Analysis (LDA). ORL face  
292 database consisting of ten different images each for 40 distinct subject is used for both  
293 training and testing. Three hundred and sixty images were used for training while forty  
294 images were used for testing. 37 of the images were correctly recognised while 3 were  
295 wrongly recognised to achieve an accuracy of 92.5%.  
296

297 [2] investigated three PCA based face recognition system which involves PCA, PCA-ANN  
298 and BPCA (Binary PCA). They utilized 400 face images which is made up of four (4) facial  
299 expression images for 100 individuals. The experimental results revealed that PCA-ANN  
300 method achieved the best recognition accuracy of 94%.  
301

302 [1] analysed the Performance of different Support Vector Machine kernels (Radial Basis  
303 Function, Linear Function, Quadratic Function and Polynomial Function) for face emotion  
304 recognition. A local African database of 714 face emotion images consisting of seven facial  
305 expression taken twice from 51 persons was used. The results obtained using the SVM  
306 multi-class classification scheme reveals that the Quadratic Function SVM kernel performs  
307 best for face emotion recognition with an average accuracy of 99.33%. However, despite the  
308 good performance achieved with higher dimensions the computation time is high.

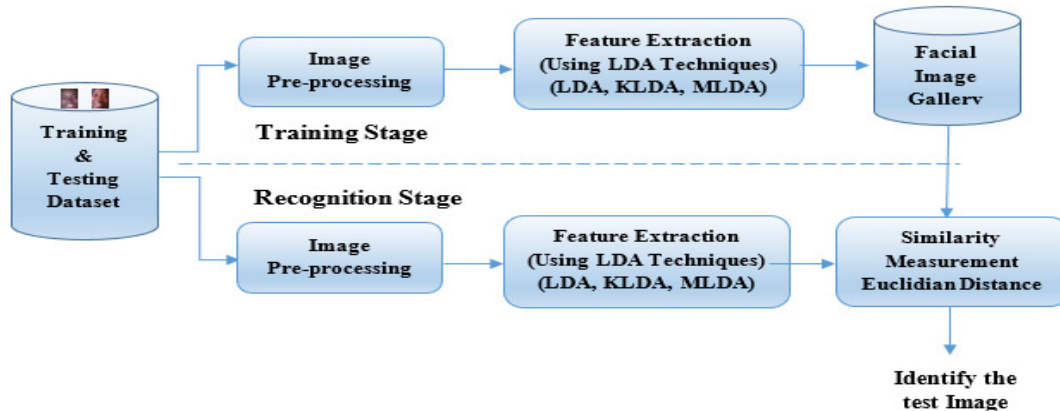

309  
 310 [33] proposed a method which involved Distance Transform on a Kernel Discriminant  
 311 Analysis DT\_KDA to extraction, and the recognition using Kohonen SOM. The work  
 312 involved two approaches. The first approach is a combination of KDA-DT-Kohonen, the  
 313 second is KDA-Kohonen and tested on two datasets: CALTECH and Computer Vision  
 314 (CE1). The second dataset is used to describe the effect of rotation of the face and  
 315 background. Extraction of facial features using KDA without DT was found to be more  
 316 accurate as the Kohonen SOM network parameters for recognizing the face at CALTECH  
 317 and CE1 dataset. The KDA-Kohonen techniques achieved 98.79% and 79.65 % using CE1  
 318 and CALTECH dataset respectively, while KDA-DT-Kohonen techniques achieved 92.78%  
 319 and 76.09 % using CE1 and CALTECH dataset respectively.

320  
 321 In the above review LDA techniques had good performance in terms of the performance  
 322 metrics used. Most of the work uses few parameters without requiring additional training or  
 323 any parameter optimization. However, most of the existing techniques have issues within  
 324 representing powerfully changing facial feature due to the fact that changing expressions of  
 325 the face are characteristically non-linear. Also, there are issues with the computational  
 326 efficiency with respect to training and testing times. Therefore, this research carried out a  
 327 comparative analysis of some selected LDA techniques. The best among these techniques  
 328 was determined based on the aforementioned performance metrics.

### 329 3. METHODOLOGY

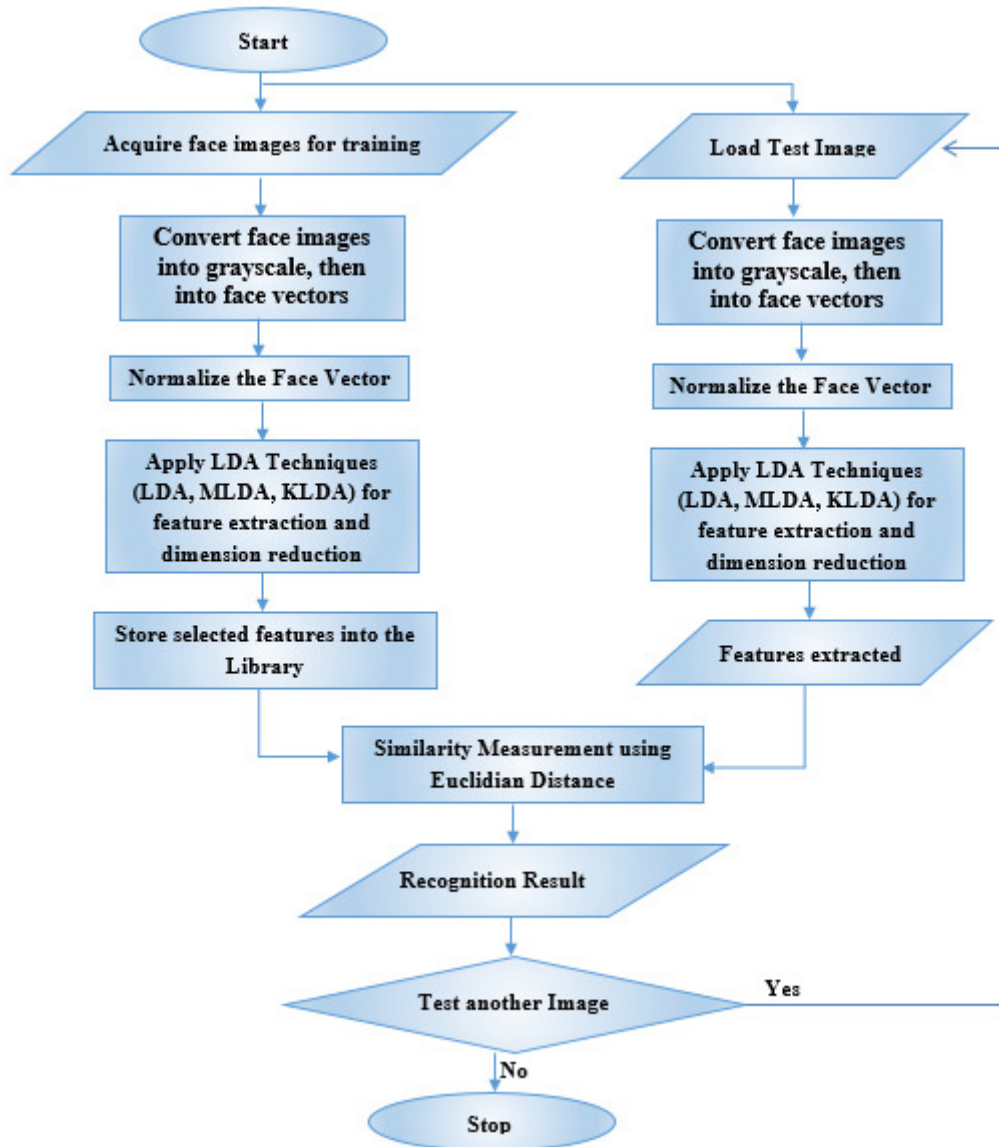

#### 330 3.1 Overview of the Methodology

331  
 332 In this paper work, three hundred and forty (340) facial images were obtained from 85  
 333 individuals (Four (4) facial expression per subject) using a digital camera. The acquired  
 334 images were divided into training dataset and testing dataset. The acquired images were  
 335 pre-processed after cropping and resizing them. Noise and other unwanted elements were  
 336 removed from the images. The coloured images were converted into gray scales for time  
 337 and memory management using function `rgb2gray` (RGB) in MATLAB Computing Toolbox.  
 338 Normalization of the images was achieved through the application of histogram equalization  
 339 techniques. The feature dimensionality reduction, separation and extraction of the pre-  
 340 processed image was achieved by the application LDA techniques (LDA, KLDA and MLDA).  
 341 Euclidian distance was used for similarity measurement between the tested images and the  
 342 trained images. The results obtained was evaluated using recognition accuracy, precision,  
 343 sensitivity, false positive rate and computation time to determine the performance of the  
 344 techniques. Figure 1 depicts the scheme for evaluating the LDA techniques while Figure 2  
 345 depicts the flowchart of the procedure for training and testing face with LDA techniques.

### 3.2 Stages of the Face Recognition Scheme

- a) **Acquisition of Face Images:** Three hundred and forty (340) images were taken with a digital camera at 1200 x 1200 pixel resolution. The images comprise of four (4) facial expression images each from eighty-five (85) individuals. The original face images were downsized into a suitable pixel. Two hundred and forty (240) of the images were used for training while the remaining One Hundred (100) were used for testing.

364 b) **Image Pre-processing:** Image pre-processing has to do with actions such as image  
365 brightness, contrast alteration, image scaling, filtering, cropping and other operations  
366 that helps in the enhancement of images. In this phase, pre-processing was carried  
367 out by converting the coloured image into grayscale and normalizing of face vectors  
368 by computing the average face vector and deducting average face from each face  
369 vector. This was done to remove noise and other unwanted element from the face  
370 images. This stage helps to get rid of unwanted information that would have been  
371 extracted as features and reduces the work to be done during dimensionality  
372 reduction (feature extraction). Grayscale conversion is necessary to reduce the  
373 number of pixels.

374 Conversion of Face Images into Grayscale and Face Vector: The image acquired  
375 from the digital camera was coloured images in three-dimensional form (3-D). The  
376 coloured images were converted into grayscale using the MATLAB function  
377 `rgb2gray` so as to reduce processing time being a two-dimensional matrix. Each of  
378 the grayscale images were expressed and stored in form of matrix in MATLAB which  
379 was converted to vector image for further processes. The conversion to face vector  
380 was made to aid the normalization process.

381 c) **Normalization of Face Image:** The normalization of the images was carried out by  
382 applying histogram equalization technique to the converted grayscale images to  
383 improve the contrast in the images by stretching out the intensity range. This  
384 enhances the brightness in the grayscale images for clearer view of the face of each  
385 subject. Normalization phase removes any common features that all the face images  
386 shared together, so that each face images is left with unique features. The common  
387 features were discovered by finding the average face vector of the whole training set  
388 (face images). Then, the average face vector was subtracted from each of the face  
389 vectors which results into a normalized face vector.

390 d) **Feature Extraction:** Significant collection of basic parameters (face features) that  
391 best illustrate the specific array of face images was extracted from the pre-  
392 processed image of each subset and was used to discriminate between them.  
393 Facials features most especially the variable part of the face such as the eyebrows,  
394 the eyelids, the nose, the cheeks and the lips will be extracted. The extracted face  
395 features was encoded and stored as weight vectors for each face images in order to  
396 compare it to other images in the training dataset. Three variants of Fisher Linear  
397 Discriminant Analysis techniques (i.e. LDA, KLDA and MLDA) were employed  
398 independently in this study to extract features (i.e. feature dimensionality reduction  
399 of the images). The resultant feature representation extracted by these techniques  
400 presented a suitable platform to identify a test image. LDA produces an optimal  
401 linear discriminant function which maps the input into the classification space in  
402 which the class identification of this sample is decided based on some metric such  
403 as Euclidean distance. Thus the objective of LDA is to find the optimal projection, so  
404 that the ratio of determinants of between-class and the within class scatter matrices  
405 of the projected samples reaches its maximum. Linear Discriminant Analysis  
406 projects into a subspace that maximizes the between class scatter while minimizing  
407 within class scatter of the projected data. LDA improves the generalization capability  
408 by decomposing into a simultaneous diagonalization of the two within- class  
409 covariance matrices. The robustness of the LDA procedure depends on whether the  
410 within-class scatter captures reliable variations for a specific class or not.  
411

### 412 413 **3.3 Euclidean Distance**

414 The extracted features by the LDA techniques i.e. LDA, KLDA and MLDA were classified  
415 using Euclidean Distance. It was employed to measure the similarity between the test vector

416 and the reference vectors in the gallery. Euclidean distance is defined as the straight-line  
 417 distance between two points. For  $N$ -dimensional space, the Euclidean distance between two  
 418 any points'  $pi$  and  $qi$  is given by equation (3.1):

$$D(x, y) = \sqrt{\sum_{i=1}^N (x_i - y_i)^2} \quad (3.1)$$

419 Where  $x_i$  and  $y_i$  is the coordinate of  $x$  and  $y$  in dimension  $i$ .

### 420 421 **3.4 Evaluation Measures**

422 The performance of the variants of LDA techniques on both trained and recognized faces  
 423 was evaluated based on recognition accuracy, false positive rate, sensitivity, specificity and  
 424 average recognition time. Confusion matrix was used to determine the value of the  
 425 performance metrics. It contains "True Positive (TP), False Positive (FP), False Negative  
 426 (FN) and True Negative (TN)." TP contains amount of entries for the tuple that correctly  
 427 identified as positive. FP contains the amount entries for the tuples which are negative but  
 428 predicted as positive. TN is the number of tuples that are negative and predicted as  
 429 negative. FN is the number of tuples that are positive but predicted as negative. Sensitivity,  
 430 specificity and accuracy will be calculated using these terms.

$$\text{Sensitivity} = \frac{TP}{TP + FN} \quad (3.2)$$

$$\text{Specificity} = \frac{TN}{TN + FP} \quad (3.3)$$

$$\text{False Positive Rate} = \frac{FP}{TN + FP} = 1 - \text{Specificity} \quad (3.4)$$

$$\text{Overall Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (3.5)$$

$$\text{Average recognition time} = \frac{\text{Total Recognition Time}}{\text{Number of recognized faces}} \quad (3.6)$$

431 The graphical representation of the relationship between the dimension size and the average  
 432 training time as well as that of threshold values and the recognition time was plotted by MS-  
 433 excel (2016). The regression analysis base on the computation time against the dimension  
 434 size and the threshold values was also conducted using MS-excel (2016). Furthermore, the  
 435 IBM SPSS Statistic version 21 was used to conduct the statistical analysis.

### 436 437 **3.4 Implementation in MATLAB**

438 The applied techniques were implemented using MATLAB R2015a version on Windows 10  
 439 Enterprise 64-bit operating system, Intel®Pentium® CPU T4500@2.30GHZ Central  
 440 Processing Unit, 4GB RAM and 500 Gigabytes hard disk drive. An interactive Graphic User  
 441 Interface (GUI) was developed with a real time database consisting of 340 face images. The  
 442 techniques will be evaluated based on the aforementioned performance metrics. The model  
 443 was experimented by taken into consideration the face recognition in 50 by 50, 100 by 100,  
 444 150 by 150 and 200 by 200-pixel resolution.

## 445 446 **4. RESULTS AND DISCUSSION**

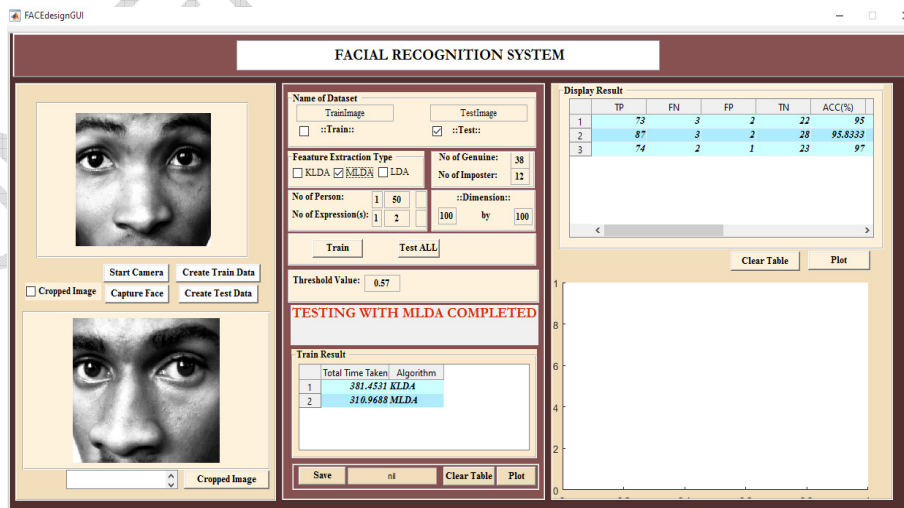

### 447 448 **4.1 Summary of results**

449 A couple of screenshots of the GUI of the implementation environment (MATLAB) is  
 450 depicted Figures 3 and 4. The time spent by each LDA technique for training the dataset is  
 451 shown in Table 1(a), Table 1(b) and Table 1(c). The time spent increases as the dimension

452 size of the images increases, which implies that the time consumed depends on the features  
 453 in the training set for LDA, KLDA and MLDA. The average training time generated by  
 454 application of LDA after two trial for images at 50 by 50 pixel resolution is 469.16 s, 100 by  
 455 100 pixel resolution is 591.42 s, 150 by 150 pixel resolution is 908.92 s, 200 by 200 pixel  
 456 resolution is 1311.76 s as presented in Table 1(a). Similarly, the average training time  
 457 generated by application of KLDA for image of at 50 by 50 pixel resolution is 488.46 s,  
 458 100 by 100 pixel resolution is 618.05 s, 150 by 150 pixel resolution is 977.15 s, 200 by 200  
 459 pixel resolution is 1393.24 s as presented in Table 1(b). Also, the average training time  
 460 generated by application of MLDA for image of at 50 by 50 pixel resolution is 431.47 s,  
 461 100 by 100 pixel resolution is 550.97 s, 150 by 150 pixel resolution is 855.12 s, 200 by 200  
 462 pixel resolution is 1191.55 s as presented in Table 1(c). The result shows that the MLDA  
 463 among other is less computationally expensive in terms of training time compared to the  
 464 LDA and KLDA model.

#### 4.2 Experimental results

The LDA, KLDA and MLDA model were experimented by implementing the facial expression recognition using 200 x 200-pixel resolution. The system was tested and evaluated using the following performance metric: sensitivity, specificity, false positive rate, recognition accuracy and computation time. All performance metrics were analysed by using a square dimension pixel resolution stated above at different threshold values.

**Table 1: Average Training Time at Different Resolutions for LDA, KLDA and MLDA**

Table 2(a) presented the result obtained by the MLDA at 200 x 200-pixel resolution at threshold value of 0.25, 0.35, 0.46 and 0.57 with respect to the performance metrics. The table reveals that the performance of MLDA varies with change in the threshold value. Also, it was discovered that accuracy, specificity increases with increase in threshold value while the false positive rate and sensitivity decreases with increase in the threshold value. However, the optimum performance was achieved at threshold value of 0.57. The MLDA achieved a false positive rate of 3.33%, sensitivity of 97.14%, specificity of 96.67% and accuracy of 97.0% at 58.65 seconds. The table also shows that the computation time is within the range of 57.56 to 59.65 seconds with increase in the threshold values.

Table 2(b) presented the result obtained by the KLDA at 200 x 200-pixel resolution at threshold value of 0.25, 0.35, 0.46 and 0.57 with respect to the performance metrics. The table reveals that the performance of KLDA varies with change in the threshold value. Also, it was discovered that accuracy, specificity increases with increase in threshold value while the false positive rate and sensitivity decreases with increase in the threshold value. However, the optimum performance was achieved at threshold value of 0.57. The KLDA achieved a false positive rate of 6.67%, sensitivity of 95.71%, specificity of 93.33% and accuracy of 95.0% at 63.67 seconds. The table also shows that the computation time is within the range of 63.63 to 64.89 seconds with increase in the threshold values.

Table 2(c) presented the result obtained by the LDA at 200 x 200-pixel resolution at threshold value of 0.25, 0.35, 0.46 and 0.57 with respect to the performance metrics. The table reveals that the performance of LDA varies with change in the threshold value. Also, it was discovered that accuracy, specificity increases with increase in threshold value while the false positive rate and sensitivity decreases with increase in the threshold value. However, the optimum performance was achieved at threshold value of 0.57. The LDA achieved a false positive rate of 6.67%, sensitivity of 92.86%, specificity of 93.33% and accuracy of

551 93.0% at 67.98 seconds. The table also shows that the computation time is within the range  
 552 of 67.89 to 68.45 seconds with increase in the threshold values.

553

554 **4.2.4 Comparison Results between MLDA, KLDA and LDA**

555 Table 3 shows a combined result of MLDA, KLDA and LDA at the threshold value of 0.57  
 556 with respect to all metrics at 200 by 200-pixel resolution. All result obtained in Table 3  
 557 presume that MLDA model has a lower recognition time compared with the corresponding  
 558 KLDA and LDA model irrespective of threshold value.

559

560 Similarly, Recognition accuracy, sensitivity, false positive rate and specificity of MLDA, KLDA  
 561 and LDA model are compared at 200 by 200-dimensional size; the study discovered that  
 562 MLDA model has better performance in accuracy, specificity and false positive rate than  
 563 KLDA and LDA model as enumerated in Table 3. The recognition accuracy of 97.0% with  
 564 MLDA, 95.0% with KLDA and 93.0 % with LDA model. The MLDA model have a specificity  
 565 of 96.67%, false positive rate of 3.33% and sensitivity of 97.14% at 58.65; the KLDA model  
 566 have a specificity of 93.33%, false positive rate of 6.67% and sensitivity of 95.71% at 63.67  
 567 while the LDA model have a specificity of 93.33%, false positive rate of 6.67% and sensitivity  
 568 of 92.86% at 67.98. Hence, MLDA outperformed KLDA and LDA.

569

570 **Table 3: MLDA, KLDA and LDA at 200 x 200-pixel Resolution and 0.57 Threshold**

571

Algorithm	FPR (%)	Sensitivity (%)	Specificity (%)	Accuracy (%)	Recognition Time (sec)
MLDA	3.33	97.14	96.67	97.00	58.65
KLDA	6.67	95.71	93.33	95.00	63.67
LDA	6.67	92.86	93.33	93.00	67.98

572

573

574 **4.3 Discussion of Results**

575

576 The experimental results discussion in terms of training and recognition computation time  
 577 analysis, evaluation of other performance metrics and statistical analysis is presented in this  
 578 section.

579

580 **4.3.1 Computation Time Analysis**

581 The results shown in Table 1 shows that the MLDA model trains the dataset much faster  
 582 than the KLDA and LDA model. Therefore, the MLDA is less computationally expensive  
 583 compared to both KLDA and the LDA model. The training time increases with increase in the  
 584 features of the training set. Figure 5 shows the graph of average training time against the  
 585 dimension size. The relationship between the average training time ( $T_t$ ) and the dimension  
 586 size ( $dm$ ) is found to be linear with a high correlation coefficient for MLDA, KLDA and LDA  
 587 model as shown in equations 4.1, 4.2 and 4.3 respectively.

$T_t = 0.0207dm + 369.02 \quad R^2 = 0.9967 \quad (4.1)$

$T_t = 0.0247dm + 405.84 \quad R^2 = 0.9962 \quad (4.2)$

$T_t = 0.0229dm + 390.44 \quad R^2 = 0.997 \quad (4.3)$

588 Similarly, Figure 6 shows the graphs which depict the relationship between the average  
 589 recognition time and the threshold values for MLDA, KLDA and LDA model respectively.  
 590 From the graph; the relationship between the recognition time ( $T_R$ ) and the threshold values  
 591 ( $th$ ) is found to be quadratic with a high correlation coefficient for MLDA and polynomial of  
 592

593 the third order with a high correlation coefficient for both KLDA and LDA model as shown in  
 594 equation 4.4, 4.5 and 4.6 respectively.

$$T_R = -29.849th^2 + 64.566th + 53.18 \quad R^2 = 0.9915 \quad (4.4)$$

$$T_R = 260.75th^3 - 327.61th^2 + 127.17th + 49.332 \quad R^2 = 0.9999 \quad (4.5)$$

$$T_R = 143.86th^3 - 182.42th^2 + 72.621th + 59.21 \quad R^2 = 0.9999 \quad (4.6)$$

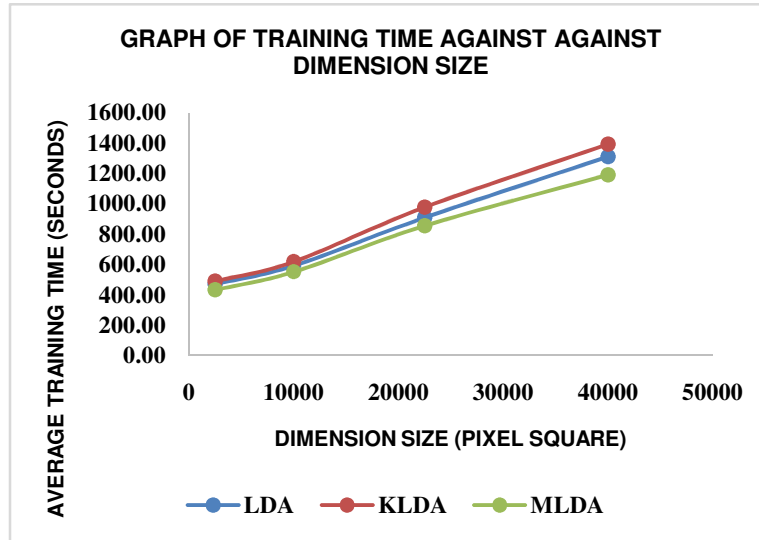

Figure 5: Relationship between Average Training Time (seconds) and Dimension size (Pixel Square)

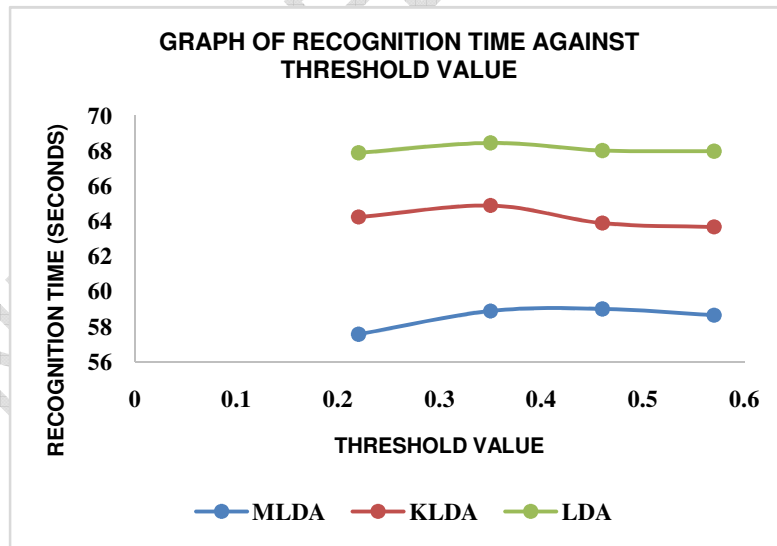

Figure 6: Relationship between Recognition Time and Threshold Values

With the computation time analysis, it was discovered that MLDA is less computationally expensive in terms of training and time recognition time compared to KLDA and LDA. The KLDA used more time to train the dataset.

#### 643 **4.6.2 Discussion Based on Performance Metrics**

644 The results obtainable in Table 2 show the performance of MLDA, KLDA and LDA model.  
645 The results show that there is significant variation in the performance metrics with increase  
646 in threshold value and the best result is obtained at the threshold value of 0.57 across all  
647 metrics (false positive rate, specificity, sensitivity and accuracy) for MLDA, KLDA and LDA.  
648 Therefore, the performance of these techniques is dependent on the threshold value. It can  
649 be inferred from the results based on the performance metrics that the MLDA model gave an  
650 increased 2.0% recognition accuracy, 3.34% specificity, 1.43% sensitivity and a decreased  
651 FPR of 3.34% over the KLDA model at 0.57 threshold value. Similarly, MLDA model gave an  
652 increased 4.0% recognition accuracy, 3.34% specificity, 4.28% sensitivity and a decreased  
653 FPR of 3.34% over the LDA model at 0.57 threshold value. Hence, MLDA outperformed  
654 KLDA and LDA in terms of FPR, recognition accuracy, specificity and sensitivity.  
655

656 The result achieved in this study is in line with the work of [24] which states that the variation  
657 in each of the variant of linear discriminant-based algorithms will have a varying performance  
658 in face recognition application due to improvement on the basic LDA. The results reveal that  
659 both KLDA and MLDA outperformed the basic LDA with MLDA having the optimum  
660 performance. Hence, the improvement on basic LDA improves the performance in facial  
661 recognition system. Nevertheless, the work of [11] proved otherwise. They reported that  
662 other two classes of LDA outperformed the multi-class LDA.  
663

664 In view of the results, the MLDA is more accurate, specific and sensitive with minimal false  
665 positive than KLDA and LDA. Therefore, MLDA gave an improved accuracy, Sensitivity,  
666 specificity and false positive rate than KLDA and LDA.  
667

#### 668 **4.6.3 Statistical Analysis of Facial Recognition Rates**

669 Statistical analysis was conducted on the result obtained in this study. Accuracy and  
670 sensitivity were considered for analysis. The result in Table 2 shows that the MLDA has a  
671 higher recognition rate than the corresponding KDLA and LDA. A t-test values was  
672 measured between the accuracy of MLDA and KLDA as well as MLDA and LDA. The paired  
673 t-test analysis conducted between accuracy of MLDA and KLDA reveals a small mean  
674 difference ( $\mu = 1.50$ ). Nevertheless, the result confirmed that the MLDA is statistically  
675 significant at  $< 0.05$ ;  $P = 0.014$  and  $t$  value = 5.196. Also, a t-test values was measured  
676 between the accuracy of MLDA and LDA. The paired t-test analysis conducted between  
677 MLDA and LDA reveals a small mean difference ( $\mu = 3.75$ ). Nevertheless, the result  
678 confirmed that the MLDA is statistically significant at  $< 0.01$ ;  $P = 0.001$  and  $t$  value = 15.0.  
679 The t-test result further validates the fact the MLDA outperformed both KLDA and LDA in  
680 terms of recognition accuracy. Furthermore, a t-test values was measured between the  
681 sensitivity of MLDA and KLDA as well as MLDA and LDA. The paired t-test analysis  
682 conducted between MLDA and KLDA reveals a small mean difference ( $\mu = 1.93$ ).  
683 Nevertheless, the result confirmed that the MLDA is statistically significant at  $< 0.01$ ;  $P =$   
684  $0.007$  and  $t$  value = 6.686. Also, a t-test values was measured between the sensitivity of  
685 MLDA and LDA. The paired t-test analysis conducted between MLDA and LDA reveals a  
686 small mean difference ( $\mu = 3.925$ ). Nevertheless, the result confirmed that the MLDA is  
687 statistically significant at  $< 0.01$ ;  $P = 0.002$  and  $t$  value = 11.056. The t-test result further  
688 validates the fact the MLDA outperformed both KLDA and LDA in terms of sensitivity.  
689

## 690 **5. CONCLUSION**

691  
692 This paper evaluated the essential features of variant of LDA face recognition system. Two  
693 hundred and forty (240) facial images were trained and One Hundred (100) images were  
694 used to test each of the LDA techniques model at different threshold value. The  
695 experimental results obtained revealed that MLDA outperformed the KLDA and LDA in terms

696 of recognition accuracies, specificity, FPR, training and recognition computation time. In view  
697 of this, a face recognition system based on MLDA would produce a more reliable security  
698 surveillance system than KLDA and LDA. It should be considered in building a truly robust  
699 face recognition system where high recognition accuracy and computational efficiency must  
700 not be compromised. Future work can be carried out by investigating the performance of  
701 each of variant of LDA on a classifier such as Support Vector Machine (SVM), Artificial  
702 Neural network (ANN), Hidden Markov Model (HMM) and others. Furthermore, the  
703 performance of Hybrid of MLDA and a suitable evolutionary search algorithm like Ant Colony  
704 Optimization (ACO), Evolutionary Programming (EP), Genetic Programming (GP),  
705 Differential Evolution (DE) and Artificial Immune Systems (AIS) can be considered as subject  
706 for future research.
