

RESISTANT GENES OF MICROBES ASSOCIATED WITH ABATTOIR WASTES

ABSTRACT

Antimicrobial drug resistance has become prominent as a universal health threat. This has been studied not only in humans but food animals as well. Many genes located on the chromosomal DNA of bacteria have been linked with drug resistance. It is therefore crucial that its occurrence in abattoirs where these animals are slaughtered be studied. This study was thus aimed at identifying some resistance genes in microbes isolated from abattoir ecologies. One hundred and eighty (180) samples consisting of service water, waste blood, wastewater, soil and faecal matter collected from Iwofe, Rumuodumaya and Trans-Amadi abattoirs within a period of one year were used in this study. Processing of the samples was done using standard microbiological protocols and the antibiotics sensitivity profile of the isolated bacteria determined using popularly consumed antibiotics. The presence of Beta-lactamase genes was checked for in the multidrug resistant isolates after they had been identified using molecular biological technique. Two strains of *Escherichia coli* had the *bla*CTX-M gene, *Pseudomonas* sp. strain 6174 had the *bla*SHV and *bla*TEM genes, *Bacillus amyloliquefaciens* had the *bla*SHV gene, *Bacillus flexus* had the *bla*TEM genes, *Staphylococcus aureus* had *bla*SHV and *bla*TEM genes. *bla*SHV, *bla*CTX-M and *bla*TEM genes were found in most of the Gram negative bacteria as *Klebsiella* sp. strain EIKU11 showed prominence of all three β -lactamase genes. This brings to light that some microbes in abattoir environments possess the β -lactamase genes which enable these microorganisms exhibit multidrug resistance, thereby making treatment resulting from them difficult. Adequate sanitary measures should thus be carried out to reduce the spread of these organisms to humans.

Introduction

In nature, antibiotics are used in the protection of human and animal health or as food additives in enhancing animal growth rate. However, most of these antibiotics are excreted from the animals to the environment. This exposes the aquatic environment to impacts of the antibiotic remnants including antibiotic resistance ([1]; [2]). This is largely due to the failure of regulatory agencies in controlling drug use, as such these drugs are obtained over-the-counter without the supervision of prescription by a licensed veterinary doctor ([3]; [4]). The risk involved is the possibility of transmission of the resultant resistant bacteria from the environment to humans either through indirect or direct contact [5]. According to previous studies, domestic animals and environments are huge reservoirs of antibiotic resistant bacteria and resistant genes which can be transferred to humans directly from animals to humans, indirectly through food or due to the deposition of animal wastes on land ([6]; [7]; [8]; [9]). Often times, antibiotics are administered to animals in order to treat infections, enhance their performance or enhance growth [10].

Antibiotics resistance however, refers to the mechanism by which microorganisms become resistant to an antibiotic which include degrading of the antimicrobial substance, modification of the chemical structure of the antibiotic, over-secretion of the target enzyme, obtaining alternate pathways to those drugs that can inhibit or cause changes in the bacterial cell permeability restricting the access of the antimicrobial agent to the target site, active removal of the antibiotic from the bacterial cell and remodeling of the target for the antibiotic [11]. Genes associated with microbial antibiotic resistance has been found in different environments at quantities higher than those present before antibiotics were mass-produced [12]. These antibiotic resistance genes (ARGs) are unique contaminants in that, they are of biological origin and can be transferred through genetic processes into different types of organism regardless of distance. Also, their source(s) could be agriculture, wastewater treatment plants or animal farms [13]. Although antibiotic resistant β -lactamases only became popular when

36 clinical resistance surfaced, spontaneous mutation alone cannot be implicated in the prevalence and
37 spread of microbial resistance to modern antibiotics ([14; 15]).

38 The emergence and selection of resistance in bacteria from animals subjected to antibiotic regimens
39 suggests that after the introduction of veterinary antibiotics, the resistance in pathogenic and faecal
40 bacteria has increased [10]. More often, these animals fall ill, they are treated with antibiotics and in
41 some cases, they pick up the antibiotics during open grazing which exposes them to antibiotic
42 resistant microorganisms [16]. Antibiotic resistance among microorganisms isolated from cows has
43 been studied especially to tetracycline, neomycin, virginiamycin and tylosin [17]. The use of
44 antimicrobials in agricultural animals causes metabolic disturbance, affecting various biochemical
45 processes and pathways including nitrogen excretion and protein synthesis. This disturbance in the
46 intestinal tract can both negatively affect the animal and result in the selection or emergence of
47 Antibiotic Resistant Organisms (AROs) in the affected species. In this case, the impact on the
48 microbiome is the result of veterinary antibiotic use [18]. Research has shown that an estimated 50-
49 90% of administered drugs to farm animals are excreted un-metabolized or as metabolic
50 intermediates into the environment, which although are inactive and may be transformed to active
51 forms in the environment increasing the risk of drug resistance [19].

52 According to Lin *et al* [20] multiple mechanisms for antibiotic resistance exists which can be coded for
53 by either single or multiple genes. These mechanisms start first with random mutation in an organism
54 which later spreads to other organisms through the process of gene transfer [13]. Horizontal gene
55 transfer (HGT) occurs through transduction, transformation and conjugation [21]. Conjugation takes
56 place when DNA transferred to a cell through direct cell contact or through a multi-protein conjugative
57 complex [22]. Transformation occurs by the take up of exogenous DNA by an organism while bacterial
58 transduction takes place when a bacteriophage injects a DNA into a bacterial cell ([23]; [24]). Either of
59 these mechanisms aids gene transfer from the environmental gene pool consisting of genetic
60 information that can be reached by more than one species of bacteria [25].

61 Resistance to extended Spectrum β -lactam drugs such as ceftriaxone, cefotaxime and Ceftazidime
62 which are 3rd generation Cephalosporins by Enterobacteria especially, has been reported as a result
63 of the promiscuous use of these antibiotics [26]. However, in recent time, resistance to these drugs
64 has been reported owing to the secretion of extended spectrum beta-lactamases in Enterobacteria
65 ([27]; [26]). The secretion of Extended-Spectrum Beta-Lactamases (B-LACTAMASEs) as an antibiotic
66 resistance mechanism to third generation Cephalosporins, is frequent among bacteria of the
67 Enterobacteriaceae family such as *Escherichia coli* and *Klebsiella pneumoniae* [28]. Microorganisms
68 which are ESBL resistant are often resistant to antibiotics of phenicols, aminoglycosides, potentiated
69 sulfonamides and fluoroquinolone class ([29]; [26]). Subsequently, β -lactamase resistant bacteria
70 have also been termed multi-drug resistant microbes. Infections caused by these β -lactamase-
71 resistant bacteria thus have limited therapeutic options as the bacteria exhibit multidrug resistance
72 [30].

73 In the past, bacteria producing β -lactamase was only found in humans; however recently, they have
74 been observed in livestock which has led to monitoring researches carried out on animals [31]. These
75 observations have led to the assumption that livestock especially food-producing animals may be
76 reservoirs of infection sources of β -lactamase-producing bacteria [29]. β -lactamase-resistant bacteria
77 residing as commensals in the intestinal tract of food-producing animals may be deposited in the
78 environment leading to the spread of β -lactam resistance encoding genes. This study was thus aimed
79 at determining the presence of some resistant genes in microorganisms isolated from abattoir wastes
80 in Port Harcourt as there exists paucity of data on this.

81 **Materials and Methods**

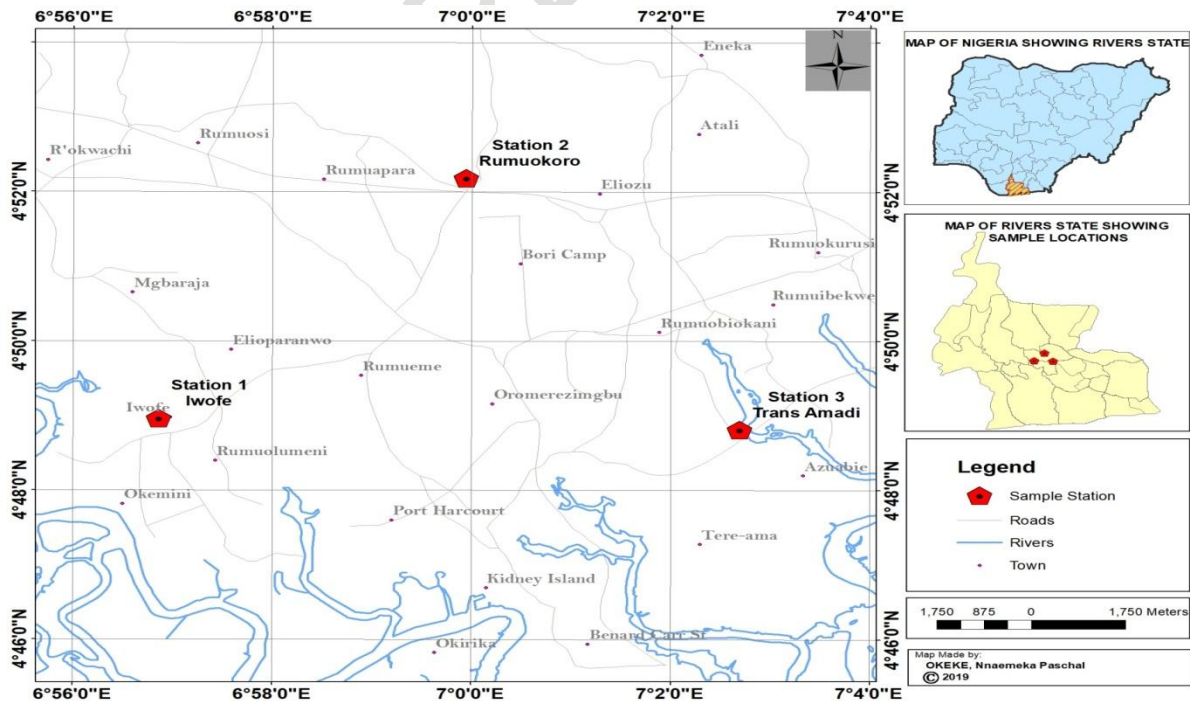

82 **Description of Study area**

83 Samples for this study were collected from abattoirs within Port Harcourt which is one of Nigeria's
 84 busiest and most populous cities. The abattoirs are located at Rumuodumaya, Iwofe and Trans-
 85 Amadi. The Trans-Amadi abattoir is Port Harcourt's largest abattoir. Its effluents are drained into the
 86 Okpoka Creek. The Creek passes through Woji, Oginigba and Azubiae communities where activities
 87 such as dredging, bathing, fishing, disposal of excreta, swimming and navigation are carried out;
 88 these abattoir effluents thus affect the activities carried out along this Creek. It is located at latitude
 89 007 2.303E and longitude 04 48.442 N. Rumuodumaya abattoir is located at longitude 04 '52' 48.0 N
 90 and latitude 7'58'20.0 E. The Iwofe abattoir has only existed for less than three years and is located at
 91 latitude 4 59'14.0N and longitude 7 16' 12.0 E. Inhabitants of these areas are mainly traders, artisans,
 92 civil servants, fishermen and farmers. Table 1 shows the GPS coordinates of the sampling points
 93 while figure 1 is a map showing the sampling locations. The samples were collected within one year
 94 covering both dry and wet seasons.

95 **Table 1: Sampling points, GPS Coordinates and Types of Samples**

Sampling stations	Sampling points	Sampling coordinates		Samples
		Northing	Easting	
Iwofe abattoir	1	004° 48.598'	006° 58.517'	Blood
	2	004° 48.592'	006° 58.501'	Soil
	3	004° 48.601'	006° 58. 525'	Water
	4	004° 48.594'	006° 58.518'	Faecal matter
	5	004° 48.598'	006° 58.517'	Waste water
Rumuodumaya abattoir	1	004° 52.118'	006° 59.580'	Blood
	2	004° 52.102'	006° 59.571'	Soil
	3	004° 52.124'	006° 59. 602'	Water
	4	004° 52.120'	006° 59.582'	Faecal matter

Figure 1: Map of Port Harcourt Metropolis showing the sampling points

100 **Sample collection**

101 Water samples used in servicing the abattoir was collected using sterile containers. The taps were
102 allowed to run for 30 seconds from the water source before the samples were collected. The cow
103 faecal matter was scooped from the intestine of the animal using sterile spatula and put in sterile
104 sample bottles while waste blood samples from the cow was collected with sterile syringes as it
105 gushed out through the vein during slaughtering. Blood for physicochemical analyses were collected
106 using sterile 1 litre sample bottles. Wastewater samples were collected after the cow carcasses were
107 washed using one litre sterile sample containers while composite soil samples (500 g) were collected
108 in sterile sample bottles with the aid of a hand soil auger at 0-15cm depth.

109 **Microbiological analyses**

110 The samples were analyzed using standard microbiological procedures [32]. One milliliter of the water
111 sample was added to 9 ml of saline solution and then a 10-fold serial dilution was done. The process
112 was repeated for the blood samples. For the faecal samples, 1g was added to pre-sterilized and
113 cooled 5 ml bacteriological peptone before serial dilution was carried out. Water samples were diluted
114 to 10^{-3} , blood to 10^{-3} , wastewater, soil and faecal to 10^{-6} . These dilutions were determined after a
115 pretest was carried out to determine the dilution at which the counts will be less than 300. Aliquots
116 (0.1 ml) of various dilutions were transferred to prepared, cooled and surface-dried Nutrient agar
117 plates.

118 **Antibiogram of Bacterial isolates**

119 The antibiotic sensitivity profile of the isolates was determined using the disc diffusion method.
120 Multiple antibiotics sensitivity discs containing eight different antibiotics including Gentamicin (10µg),
121 Ceftriaxone (30 µg), Erythromycin(5 µg), Cloxacillin (5 µg), Ofloxacin (5 µg), Augmentin (30 µg),
122 Ceftazidime (30 µg), Cefuroxime (30 µg), Nitrofurantoin (300 µg), Cefixime (5 µg) and Ciprofloxacin (5
123 µg). on each ring were used. Mueller-Hinton agar was used as the culture medium for the tests [32].
124 The zones of inhibition were measured using a graduated metre rule, recorded in millimetres and the
125 values compared with the CLSI standards to determine the level of resistance or susceptibility of the
126 isolates to the antibiotics [33]

127 **Molecular Identification**

128 Molecular identification of the isolates that exhibited multiple antibiotics resistance was done using the
129 Polymerase chain Reaction (PCR) to determine the 16S rRNA sequence. This was done by first
130 extracting the DNA, carrying out the PCR and sequencing of the amplified DNA (amplicon).

131 **Extraction (Boiling Method) and Quantification of DNA**

132 An 18-hour old culture of the bacterial isolate was transferred to Luria Bertani (LB) and incubated
133 overnight. From this overnight broth, 5 ml was transferred to an Eppendorf tube and spun for 3
134 minutes at 14000 rpm. The sediment which was made up of the cells were resuspended in 1 ml of
135 normal saline and heated for 20 mins at 95 °C. This heated suspension was further cooled on ice and
136 spun in a centrifuge at 14 rpm for 3 minutes. The supernatant which contained the DNA was
137 transferred to a 1.5 ml microcentrifuge tube and kept at 20 °C pending further reactions [34]. Using a
138 Nanodrop 1000 spectrophotometer, the extracted genomic DNA was quantified.

139 **Amplification of 16S rRNA**

140 Using the 27F (5'-AGAGTTTGATCMTGGCTCAG-3') and 1492R (5'-CGGTTACCTTGTTACGACTT-3')
141 primers on an ABI 9700 Applied Biosystems Thermal cycler, the 16S rRNA region of the rRNA of the
142 bacterial isolates were amplified. A final volume of 50 µl was used for 35 cycles in the reaction
143 process. The PCR mix was made up of 0.4 nM of primers, X2 Dream taq Master mix (Inqaba, South
144 Africa) and the template which was the extracted DNA (50 ng). The Master mix was made up of
145 Magnesium Chloride (MgCl₂), taq DNA polymerase and dNTPs (Deoxyribonucleotides). The
146 conditions for the reaction were Initial denaturation at 95 °C for 5 minutes, denaturation at 95 °C for
147 30 seconds, annealing at 52 °C for 30 seconds, extension at 72 °C for 30 seconds and final extension
148

154 at 72 °C for 5 minutes. Resolution of the product was done on a 1% agarose gel for 15 minutes and
155 viewed on a UV transilluminator. Sequencing of the amplified DNA was using the BigDye Terminator
156 kit on a 3510 ABI sequencer (Inqaba Biotechnological, Pretoria, South Africa).

157

158 **Detection of Resistance Genes**

159 Using the SHV F: 5' CGCCTGTGTATTATCTCCCT-3' and SHV R: 5'-CGAGTAGTCCACCAGATCCT-3'
160 primers, *bla*SHV genes from the isolates were amplified on a ABI 9700 Applied Biosystems thermal
161 cyclor at a final volume of 30 µl for 35 cycles. The resultant product was resolved on a 2 % agarose
162 gel at 90V for 25 minutes and visualized on a UV transilluminator for a 281 bp product size. The same
163 procedure was carried out but CTX-MF: 5'-CGCTTTGCGATGTGCAG-3' and CTX-MR: 5'-
164 ACCGCGATATCGTTGGT-3' primers were used for CTX-M gene and TEMF: 5'-
165 ATGAGTATTCAACATTTCCGTG-3' and TEMR: 5'-TTACCAATGCTTAATCAGTGAG-3' primers for
166 *bla*TEM gene [35]. Sizes of resolved products were 281 bp, 550 bp and 850 bp for *bla*SHV, *bla*CTX-M
167 and *bla*TEM, respectively.

168

169 **Results**

170 The results of the multiple drug sensitivity test for the Gram negative isolates are presented in Figure
171 2, showing that the isolates exhibited 100% resistance to Cefuroxime and a corresponding 100%
172 susceptibility to Ofloxacin. The Gram positive isolates exhibited 100% susceptibility to Ofloxacin and
173 100% resistance to Ceftazidime, Cefuroxime and Augmentin (Figure 3). Table 2 shows the microbes
174 that exhibited multidrug resistance and the drugs were resistant to. *Bacillus amyloliquefaciens*,
175 *Bacillus flexus* and *Proteus mirabilis* were resistant to Ceftazidime, Cefuroxime and Augmentin. Plates
176 1, 2 and 3 shows the agarose gel electroporesis for the amplified *bla*CTX-M, *bla*SHV and *bla*TEM
177 genes respectively. The occurrence of resistance genes among the isolates is presented in table 3.
178 *Escherichia coli* strain 2017C-4109 had the *bla*CTX-M gene, *Pseudomonas* sp. strain 6174 had the
179 *bla*SHV and *bla*TEM genes, *Bacillus amyloliquefaciens* had the *bla*SHV gene, *B. flexus* had the
180 *bla*TEM genes, *Staphylococcus aureus* had *bla*SHV and *bla*TEM genes, *Proteus mirabilis* had the
181 *bla*CTX-M and *bla*TEM genes while *Klebsiella* sp strain EIKU11 possessed all three resistance genes.

208
 209 **Discussion**

210 Microorganisms isolated in this study were of the genus *Staphylococcus*, *Pseudomonas*, *Klebsiella*,
 211 *Proteus* and *Bacillus*. Similar organisms had been isolated from abattoir environments by some
 212 authors [36-39]. These microorganisms have been implicated as pathogens of various infections
 213 including diarrhoea, bacteremia, dysentery, urinary tract infections in humans which makes them of
 214 public health importance [40]). This is especially important as several persons visit these abattoirs
 215 daily to purchase meat and its products and are thus predisposed to the health risks associated with

216 these organisms to humans. Multiple antibiotics sensitivity testing of the bacterial isolates showed
217 they exhibited a high level of susceptibility to Ofloxacin (a quinolone) and a corresponding resistance
218 to β -lactam drugs including Ceftaxidime, Cefuroxime and Augmentin. Drugs with lower Minimum
219 Inhibitory Concentrations (MICs) such as Ofloxacin and Cloxacillin exhibited lower inhibitory activity
220 against the isolates compared with those with higher MICs such as Augmentin which may be
221 attributed to the frequent use of these antimicrobial drugs for treatment of infections. Also, this trend
222 has been reported by Adesoji *et al.* [41] and Harrison and Bratcher [42], who studied the susceptibility
223 of some microorganisms from abattoir sources to some drugs including Augmentin and cefuroxime.
224 This poses a threat as treatment against infections caused by these organisms becomes difficult or
225 may take a longer time to respond against the causative agent [39]. Microbial drug resistance has
226 been reported to be linked with mechanisms such as inappropriate use of the drugs, widespread use
227 of antibiotics in the production of animal feeds, its use in treatment of infections and for prophylaxis,
228 excretion of metabolized or non-metabolized administered drugs by animals into the environment
229 which undergo transformation into their active forms ([43]; [19]; [44], [45]).

230 The resistance genes checked for in this study were *bla*SHV and *bla*TEM which are genes coding for
231 the production of β -lactamases- enzymes able to deactivate penicillin drugs and *bla*CTX-M gene
232 coding for the inactivation of extended spectrum β -lactam drugs, which are 3rd and 4th generation
233 cephalosporins [26]. The presence of these genes in enteric bacteria such as *E. coli* and *Klebsiella*
234 sp. in food-producing livestock such as cows, poses a public health risk as these organisms are
235 discharged into the environment. Spread of resistance genes through horizontal gene transfer to
236 human pathogens may occur, thereby complicating antibacterial therapy when infection occurs [27].
237 Production of β -lactamase has been noted as the commonest mechanism of resistance to 3rd and 4th
238 generation cephalosporins among enteric bacteria [28]. Studies on animal faecal samples in Ado-
239 Ekiti, Nigeria, revealed that *bla*CTX-M, *bla*SHV and *bla*TEM were detected in the isolated
240 chromosomal DNA of *E. coli* [46]. Detection of TEM gene was also reported by Igbinosa and
241 Obuekwe [47] in abattoir samples. *bla*TEM and *bla*CTX-M have been isolated from abattoir samples
242 as observed in this study [48]. These animals may thus, become reservoirs of β -lactamases thereby
243 contributing to the increased rate of antibiotic resistance.

244

245 **Conclusion**

246 This study recorded the presence of *bla*CTX-M, *bla*SHV and *bla*TEM genes that code for antibiotic
247 resistance in microorganisms isolated from abattoir environments. These microorganisms exhibited
248 multi-drug resistance to popularly consumed antibiotics including Augmentin and Ceftazidime and
249 Cefuroxime. Spread of microorganisms carrying these genes can be reduced by carrying out
250 adequate sanitary conditions in abattoir environments. From the results obtained in this study,
251 antibiotics resistant bacteria are widespread as nearly all the isolated microorganisms were resistant
252 to most of the antibiotics for which they were tested for. This may be due to either the intrinsic
253 resistance of many microorganisms to antibiotics or acquired resistance of the organisms enabled by
254 the transfer of resistance of drug resistance plasmids among members of the isolates. Since
255 antibiotics in animal feed promote animal growth, improved efficiency of feed conversion to body
256 weight, and may also affect disease prophylaxis among the confined microbes in such animals and
257 their subsequent impact on human health, it has increased its indiscriminate use [48].
