

STATISTICAL COMPARATIVE STUDY OF THE TREND AND VARIATION OF METEOROLOGICAL PARAMETERS IN ABEOKUTA, SOUTH-WEST NIGERIA

ABSTRACT

This study focuses on the statistical comparative study of the trend and variation of meteorological parameters covering a 10 year period (2001-2010) in the capital and largest city of Ogun State, Abeokuta, southwest region of Nigeria. The analyzed meteorological parameters were: wind speed, vapour pressure, relative humidity, temperature, sunshine and rainfall covering 10 years. The calculated coefficient of variation (CV) for sunshine (22.78%), wind speed (21.55%), and rainfall (99.12%) is a proof of exceedence of variability of threshold of 10% while the CV calculated for air temperature (5.74%), relative humidity (4.52%) and vapour pressure (5.22%) show no significance of variability. Significance test of meteorological parameters' trend reveals a notable reduction in the values of vapour pressure, air temperature and relative humidity. It is, however, difficult to argue for a well-defined change in most of the meteorological parameters based on the monthly time series analyses performed in this work. Only wind speed shows statistically significant increasing trend during the period of observation at 1% significance level. The trend revealed by rainfall and sunshine are statistically not significant. ANOVA test of significant difference among meteorological parameters shows a *p*-value (Sig.) of 0.000 is an indication of significant difference in the analyzed mean monthly coefficient of variation for the meteorological parameters under study. The Tukey's multiple pair comparisons test however shows that there is significant difference between the mean monthly CV of rainfall-sunshine, rainfall-vapour pressure, rainfall-wind speed, rainfall-air temperature and rainfall-relative humidity. At significance level of 5%, the calculated mean monthly CV of rainfall is significantly different from the mean monthly CV of other climatic parameters.

Keywords: Meteorological parameters, Coefficient of variation, variability threshold, significance level, significance of variability.

1. INTRODUCTION

Climate study is worth investigating since human lives is strictly attached and it is important to have knowledge of our environmental changes that we would not be caught unaware by

38 the consequences of the adverse effect offered. Climate change is associated to weather
39 conditions and it has a great effect in environmental changes. A full knowledge on the
40 environment will enhance proper management risks so as to avert disasters. It is of great
41 importance to know that improper management of climate could lead to natural disasters. It is
42 therefore imperative to introduce protective schemes through the results obtained from
43 quality research works that related with environment. Year to year variability is caused by
44 climate and has a link with socio-economic and environmental activities. It is of great
45 importance toward the development and proper planning of schemes that relates to water
46 resources such as the management of drought, the prevention and control of flood.
47 Importantly, natural and ecosystems coupled with the society as a whole are directly linked
48 to the consequences of change in climatic pattern either positively or negatively. Invariably,
49 there could be alteration in the location of the major crop production regions on the earth.

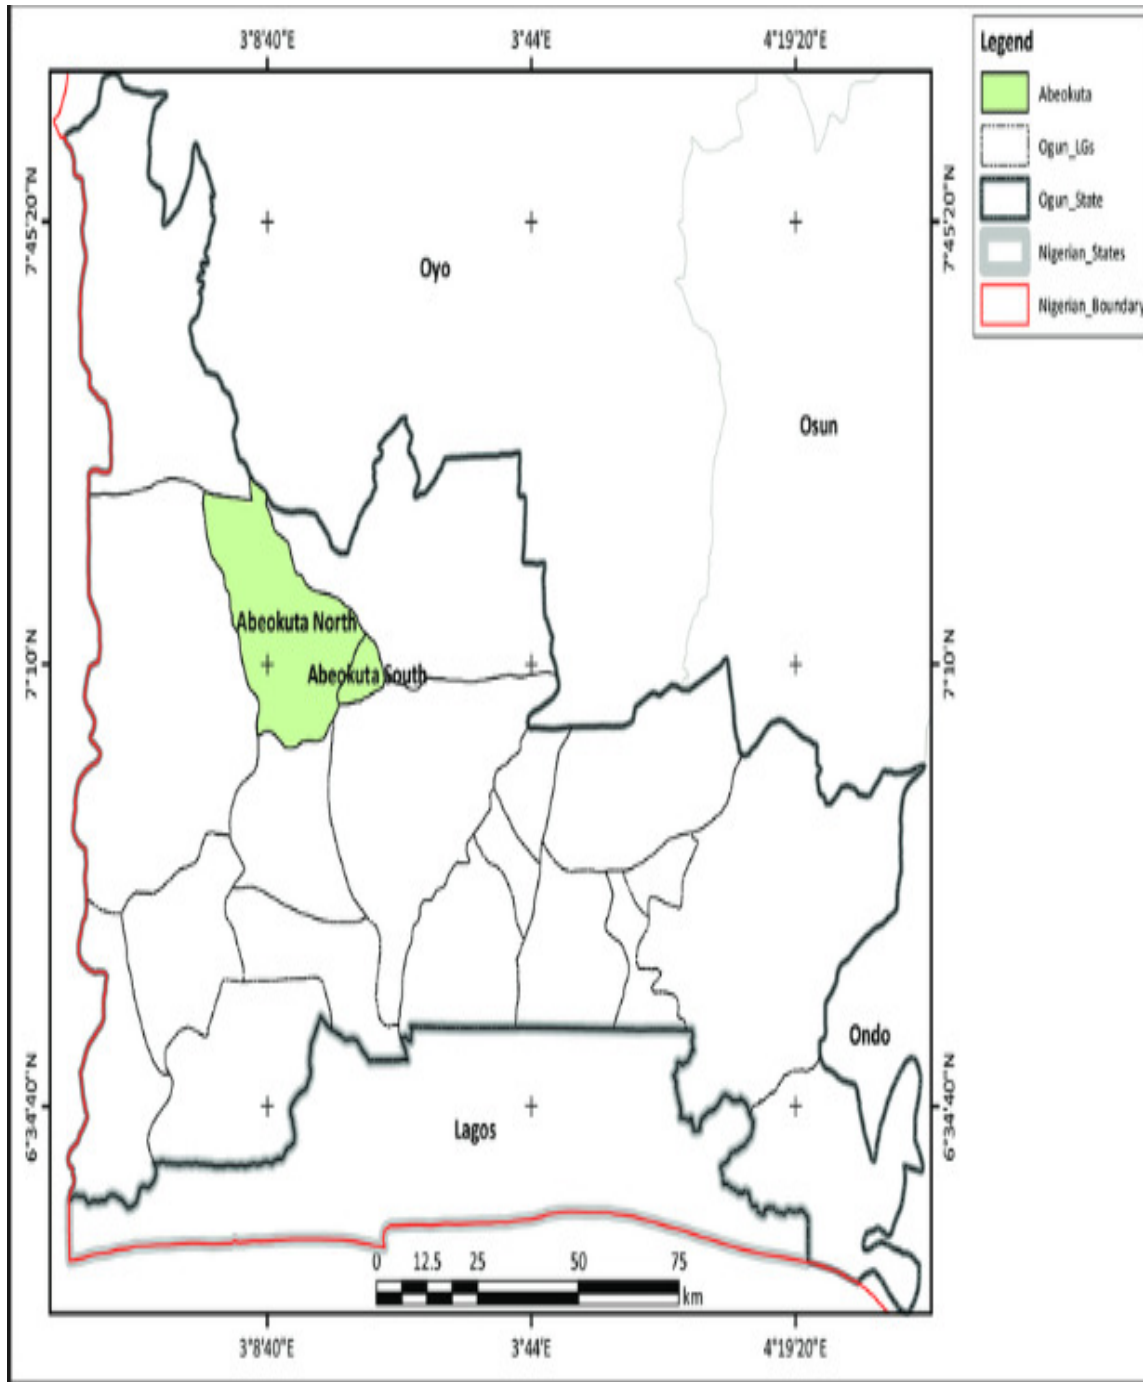

50 The variation of climate has a great influence on socio-economic activities. Research works
51 conducted by [1] and [2] show that climatic parameters are closely related and have
52 influence on crop production. Precipitation, temperature, wind, pressure and humidity are
53 physical conditions in the environment and atmosphere which are termed as weather because
54 they have direct or indirect consequences upon the biosphere while the pattern of weather in
55 a region over period of time is referred to as climate [3]. Rise in number of vehicles and
56 industries are also factors in contemporary trends in climate [3]. It was reported by [5] that it
57 is not only soil and pests that offers draw backs in crop production but the effect of climate is
58 of much influence.

59 Instability of weather could offer adverse effects in social, economic and regional
60 competitiveness [7]. The negative change in climatic pattern could be harmful to socio-
61 economic activities thereby causing reduction in food and fibers delivery to the teeming
62 population [8]. The study conducted by [10] revealed that meteorological parameters from
63 monthly series are of decreasing trend and not statistically significant except for rainfall and
64 humidity that show an increasing trend which is statistically not significant.

65 The objectives of this study are to; examine the variations in rainfall, sunshine, air
66 temperature, wind speed, relative humidity and water vapour patterns in the study area,
67 examine the statistical link between sunshine, air temperature, wind speed, relative humidity
68 rainfall and water vapour in the study area, determination of the trend of the
69 meteorological parameters and presentation of their possible effects.

72 73 **2. STUDY AREA**

74 The study area (Abeokuta) lies between longitude and latitude of $4^{\circ} 19'20''$ E and $7^{\circ}45'20''$ N
75 respectively [4]. Abeokuta lies in the wooden savanna and the surface is characterized with
76 masses of granite with grey color. It covers an extensive area being surrounded by mud walls
77 which is of 18 miles in extent [9].

84

85

86 3. METHODOLOGY

87 Ten years meteorological parameters (relative humidity, temperature, sunshine, wind speed,
88 rainfall and vapour pressure) for Abeokuta Southwest Nigeria were collected from the Nigerian

89 Meteorological Agency (NIMET) archive. The coefficient of variation was calculated as
 90 described in equation (1) by [6].

$$91 \quad CV = \left(\frac{\sigma}{MP} \right) \times 100\% \quad \text{---(1)}$$

92 The calculated monthly mean of the meteorological parameters is denoted as MP while σ is the
 93 standard deviation.

94 The statistical analysis were done using descriptive statistics, Kendall's tau_b, Spearman's rho,
 95 ANOVA and Tukey's multiple pair comparisons test. Data collected were analyzed
 96 electronically using Ms-Excel (version 2007) and SPSS (version 21.0).

97 The **Kendall's tau_b** for measuring order association between variables X and Y is given by the
 98 following formula :

$$\tau_b = \frac{P - Q}{\sqrt{D_r D_c}} \quad (2)$$

99 Where the P and Q listed above are double the "usual" P (number of concordant pairs) and Q
 100 (number of discordant pairs). Likewise, D_r is double the "usual" $P+Q+X_0$ (the number of
 101 concordant pairs, discordant pairs, and pairs on which the row variable is tied) and D_c is double
 102 the "usual" $P+Q+Y_0$ (the number of concordant pairs, discordant pairs, and pairs on which the
 103 column variable is tied).

105 The **Spearman correlation coefficient** is defined as the Pearson correlation coefficient between
 106 the ranked variables.

107 For a sample of size n , the n raw scores X_i, Y_i are converted to ranks $rg X_i, rg Y_i$, and r_s is
 108 computed from:

$$r_s = \rho_{rgX,rgY} = \frac{Cov(rgX,rgY)}{\sigma_{rgX}\sigma_{rgY}} \quad (3)$$

109 Where ρ denotes the usual Pearson correlation coefficient, but applied to the rank variables.

110 $Cov(rgX,rgY)$ is the covariance of the rank variables.

111 σ_{rgX} and σ_{rgY} are the standard deviations of the rank variables.

112 Only if all n ranks are distinct integers, it can be computed using the popular formula

$$r_s = 1 - \frac{6 \sum d_i^2}{n(n^2 - 1)} \quad (4)$$

113 Where $d_i = rg(X_i) - rg(Y_i)$, is the difference between the two ranks of each observation.

114 n is the number of observations.

116 **ANOVA** (One-way) is a technique that can be used to compare means of two or more samples
 117 (using the F distribution). The ANOVA test the null hypothesis that samples in all groups are
 118 drawn from populations with same mean values.

119 The normal linear model implemented in this study is means model which is given as :

$$120 \quad y_{ij} = \mu_j + \epsilon_{ij} \quad (5)$$

122 **Tukey's multiple pair comparisons test** compares the means of every treatment to the means of
 123 every other treatment; that is, it applies simultaneously to the set of all pairwise comparisons
 124 $\mu_i - \mu_j$ and identifies any difference between two means that is greater than the expected
 125 standard error.

126 The formula for Tukey's test is:

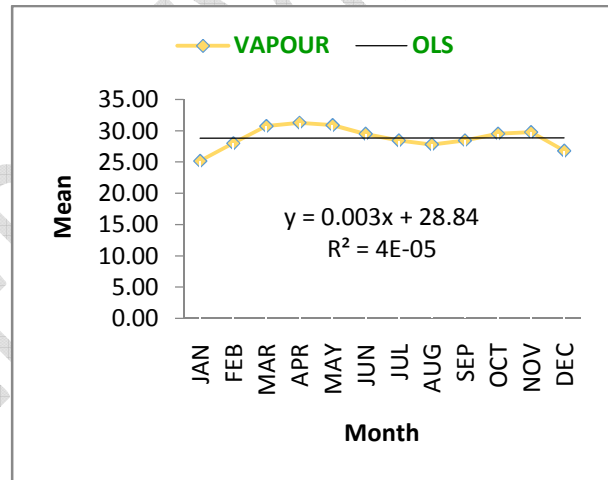

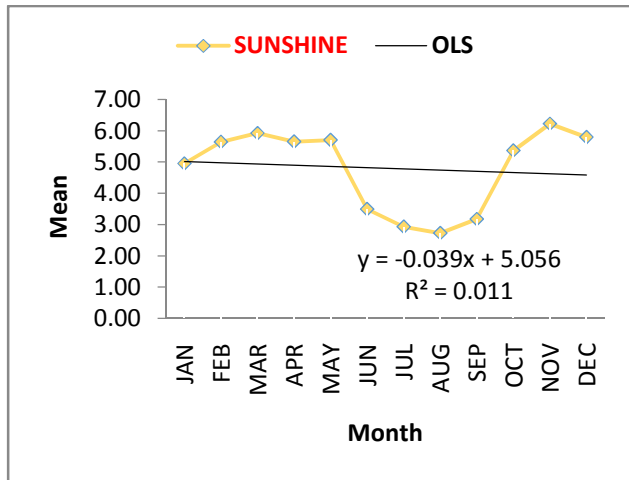

$$q_s = \frac{Y_A - Y_B}{SE} \quad (6)$$

127 Where Y_A is the larger of the two means being compared.
 128 Y_B is the smaller of the two means being compared.
 129 SE is the standard error of the two sum of the means.
 130 This q_s value can then be compared to a q value from the studentized range distribution. If the q_s
 131 value is larger than the critical value q_α obtained from the distribution, the two means are said to
 132 be significantly different at level $\alpha, 0 \leq \alpha \leq 1$.

167

168

5. DISCUSSION OF RESULTS

169 The mean monthly values and trend of the meteorological parameters in the study area are
 170 presented in Figure 2. For sunshine, months of January, February, March, April, May, October,
 171 November and December show maximum sunshine regimes. Incessant cloud formation depletes
 172 the amount of sun reaching us is accountable for the minimum sunshine experienced in August
 173 which was earlier reported by [7] for Ibadan sunshine hour in 2012. R^2 of 0.011 implies that
 174 approximately 1.1% of the variation in sunshine distribution was being explained by the monthly
 175 period of study.

176 A gradual pick up in vapour pressure was experienced in January which spans through the
 177 months of February, March and April but dropped in May. There was persistence in the trend of
 178 vapour pressure in July and August. October and November showed a rise in the vapour pressure
 179 while there was a sudden collapse in December. R^2 of 4E-05 implies that the monthly period of
 180 study does not explain a significant variation in vapour pressure distribution.

181 Unstable wind speed distribution was observed for the period under study. February and March
 182 relays peak levels of wind speed while September marked a low distribution. R^2 of 0.639 implies
 183 that approximately 63.9% of the variation in wind speed distribution is being explained by the
 184 monthly period of study.

185 Highest value of air temperature was recorded in July which eventually collapsed in August and
186 spans through August and September. Least temperature is shown in September which gradually
187 increases from the months of October to December. R^2 of 0.003 implies that approximately 0.3%
188 of the variation in air temperature distribution is being explained by the monthly period of study.
189 There is an exponential rise in relative humidity in months January, February, March, April,
190 May, June and July. August revealed upward trend movement of the relative humidity regimes
191 which later showed a trend collapse and decreased from September to December. R^2 of 0.258
192 implies that approximately 25.8% of the variation in relative humidity distribution is being
193 explained by the monthly period of study.

194 Mean monthly distribution of rainfall showed a low rainfall for the months of January, February,
195 March, November and December. There was an upward increase of rainfall from April till July.
196 A sudden collapse in the rise level of rainfall was experienced in August which later increased
197 gradually in September and dropped down from the month of October to December. R^2 of 0.033
198 implies that approximately 3.3% of the variation in rainfall distribution is being explained by the
199 monthly period of study.

200 Figure 3 & 4 shows the coefficients of variation (CV) for the meteorological parameters under
201 study. The highest values of the CV calculated for the climatic parameters sunshine, vapour
202 pressure, wind speed, rainfall, air temperature and relative humidity were: 41.84%, 17.33%,
203 28.95%, 283.23%, 7.13% and 14.63% while lowest values were: 8.01%, 1.41%, 18.04%,
204 25.62%, 5.00% and 1.16% respectively. From the obtained results, rainfall exhibits the highest
205 variation while relative humidity depicts the least variation.

206 The descriptive statistics result from Table 1, indicates that we expect the monthly CV for
207 rainfall to be 99.12%, the expected monthly CV for sunshine to be 22.78%, the expected
208 monthly CV for vapour pressure to be 5.22%, the expected monthly CV for wind speed to be
209 21.55%, the expected monthly CV for air temperature to be 5.74% and the expected monthly CV
210 for relative humidity to be 4.52%.

211 Table 2 shows bivariate correlations among the meteorological parameters using Kendall's tau_b
212 and Spearman's rho statistics. From Kendall's tau_b analysis, it shows there is a weak positive
213 association between rainfall-sunshine, rainfall-wind speed. Sunshine-vapour pressure, sunshine-
214 wind speed, vapour pressure-wind speed. Weak negative association is observed between
215 rainfall-air temperature, wind speed-relative humidity, vapour pressure-air temperature,
216 sunshine-air temperature and sunshine-relative humidity. There is an average significant
217 relationship between rainfall-vapour pressure, rainfall-relative humidity but a strong positive
218 significant correlation between vapour pressure and relative humidity at 5% significance level.
219 There is no association between air temperature-wind speed. Spearman's rho results show that
220 there is a very strong positive significant correlation between rainfall-vapour pressure, rainfall-
221 relative humidity, vapour pressure-relative humidity at 5% significance level. Negative
222 correlation is experienced between rainfall-air temperature, sunshine-air temperature, sunshine-
223 relative humidity, vapour pressure-air temperature, wind speed-relative humidity and air
224 temperature-relative humidity.

225 Significance test of meteorological parameters' trend from Table 3 reveals a notable
226 deterioration in the values of vapour pressure, air temperature and relative humidity. However, it
227 is difficult to argue for a well-defined change in most of the meteorological parameters based on
228 the monthly time series analysis performed in this work. Only wind speed shows statistically
229 significant increasing trend during the period of observation at 1% significance level. The trend
230 shows by others are statistically not significant.

231 ANOVA Test of significant difference among meteorological parameters from Table 4 shows a
232 p -value (Sig.) of 0.000 indicating a significant difference in the mean monthly coefficient of
233 variation of the six climatic parameters (rainfall, sunshine, vapour pressure, wind speed, air

234 temperature and relative humidity). In other words, the mean monthly coefficient of variation of
235 at least one of the parameters is significantly different from others.

236 The Tukey's multiple pair comparisons test from Table 5 shows that there is significant
237 difference between the mean monthly CV of rainfall–sunshine, rainfall-vapour pressure, rainfall-
238 wind speed, rainfall-air temperature and rainfall-relative humidity. It is therefore evident that the
239 mean monthly CV of rainfall is significantly different from the mean monthly CV of the other
240 climatic parameters at 5% significance level.

241 The Tukey's homogeneous subset from Table 6 shows the order of importance of the
242 meteorological parameters under study. It reveals that relative humidity is of the most important,
243 followed by vapour pressure, air temperature, wind speed, sunshine and rainfall as the least
244 important.

245

246 **6. CONCLUSION**

247

248 This study revealed the occurrence of significant difference in variation for all the investigated
249 meteorological parameters. Also, there is a notable deterioration in the values of vapour pressure,
250 air temperature and relative humidity. Only wind speed shows statistically significant increasing
251 trend during the period of observation while the trend shows by others are statistically not
252 significant. Rainfall, wind speed and temperature show tolerable values which are not life
253 threatening to the residents of Abeokuta. For vapour pressure, only months of January, August
254 and December are safe but proper precautionary measures must be infused in other months in
255 order to reduce problems of high blood pressure due to high vapour pressure. Since the relative
256 humidity is higher than the tolerable limit of 60%, Abeokuta is subject to heat .Therefore, the
257 residents should endeavor to provide themselves cooling systems for homeostasis to be engaged.
258 Also, exposure time to sunlight should also be reduced in months of November and December
259 respectively so as to avoid or reduce the aging of the skin due to excessive exposure to sunlight.
