## ABSTRACT

The greenhouse effect concept explains the Earth's elevated temperature. The IPCC endorses the anthropogenic global warming theory, and it assumes that the greenhouse (GH) effect is due to the longwave (LW) absorption by GH gases and clouds. The IPCC's GH definition lets to understand that the LW absorption is responsible for the downward radiation to the surface. According to the energy laws, it is not possible that the LW absorption of  $155.6 \text{ Wm}^{-2}$  by the GH gases could re-emit downward LW radiation of  $345.6 \text{ Wm}^{-2}$  on the Earth's surface. When the shortwave (SW) absorption is decreased from this total LW radiation, the rest of the radiation is  $270.6 \text{ Wm}^{-2}$ . This LW radiation downward is the imminent cause for the GH effect increasing the surface temperature by the  $33^\circ\text{C}$ . It includes LW absorption by the GH gases and clouds in the atmosphere and the latent and sensible heating effects. Without the latent and sensible heating impacts in the atmosphere, the downward LW radiation could not close the energy balance of the surface. The contribution of  $\text{CO}_2$  in the GH effect is 7.4% corresponding to  $2.5^\circ\text{C}$  in temperature. This result does not only mutilate the image of  $\text{CO}_2$  as a strong GH gas, but it has further consequences in climate models. It turned out that the IPCC's climate model showing a climate sensitivity CS of  $1.2^\circ\text{C}$  could not be fitted into the total GH effect of  $\text{CO}_2$ . A climate model showing a CS of  $0.6^\circ\text{C}$  matches the  $\text{CO}_2$  contribution in the GH effect.

14 **1. INTRODUCTION**

15

16 The greenhouse (GH) effect is the basic concept of the IPCC in global warming. The  
17 definition of the GH effect, according to AR5 [1], is: *“The longwave radiation (LWR, also  
18 referred to as infrared radiation) emitted from the Earth’s surface is largely absorbed by  
19 certain atmospheric constituents - (greenhouse gases and clouds) - which themselves emit  
20 LWR into all directions. The downward directed component of this LWR adds heat to the  
21 lower layers of the atmosphere and to the Earth’s surface (greenhouse effect).”*

22

23 Hartmann [2] summarizes the final details of the GH effect in this way: *“Most of this emitted  
24 infrared radiation is absorbed by trace gases and clouds in the overlying atmosphere. The  
25 atmosphere also emits radiation, primarily at infrared wavelengths, in all directions.  
26 Radiation emitted downward from the atmosphere adds to the warming of Earth’s surface by  
27 sunlight. This enhanced warming is termed the greenhouse effect.”* According to Hartmann,  
28 the atmosphere emits radiation and not only GH gases and clouds, which is an essential  
29 difference to the IPCC’s definition.

30

31 Ollila [3] has analyzed the Earth’s energy balance and the energy fluxes connected to the  
32 GH effect. His conclusion is that the IPCC’s definition violates the physical laws, because the  
33 downward LW radiation to the surface is much greater than the LW absorption by GH gases  
34 and clouds: in all-sky conditions  $345.6 \text{ Wm}^{-2}$  versus  $155.6 \text{ Wm}^{-2}$ .

35

36 Ollila has included the SW absorption by the atmosphere into the GH effect. The main  
37 objective of this study is to analyze if this is a feasible and justified conclusion.

38

39 **2. CALCULATION BASIS OF THE GREENHOUSE EFFECT**

40

41 The author has used the energy flux values of the previous study [3], and they have been  
42 depicted for illustrating the GH effect in Figure 1. In this study, only all-sky values have been  
43 applied, if not specified otherwise. The accurate flux values have been applied, even though  
44 it is known that a typical uncertainty limit is  $\pm 5 \text{ Wm}^{-2}$  [3].

49  
50

**Figure 1.** Energy fluxes contributing to the greenhouse effect in all-sky conditions (Wm<sup>-2</sup>).

51

52 In this figure is a difference in respect to the same of the previous study [3]. The SW  
53 absorption flux by the atmosphere has not been included into the GH effect. The Earth  
54 receives a net energy 240 Wm<sup>-2</sup> based on the incoming insolation and the reflected SW flux  
55 at the TOA (Top of the Atmosphere). Based on the observations the Earth's surface absorbs  
56 165 Wm<sup>-2</sup>, and therefore the atmosphere absorbs 240 – 165 = 75 Wm<sup>-2</sup>. The satellite  
57 observations confirm that the Earth radiates 240 Wm<sup>-2</sup> LW radiation into space. Because this  
58 240 Wm<sup>-2</sup> corresponds about -18°C black surface temperature and the average surface  
59 temperature is +15°C, there is a warming/isolation mechanism making this difference  
60 possible, which is called the GH effect.

61

62 The obvious reason for the GH effect seems to be the downward LW radiation from the  
63 atmosphere to the surface and its magnitude is 345.6 Wm<sup>-2</sup> (LW<sub>dn</sub>). The first question is if  
64 LW<sub>dn</sub> should be regarded to totally responsible for the GH effect as assessed earlier [3].  
65 LW<sub>dn</sub> includes the SW absorption flux by the atmosphere and it is part of the net energy  
66 received from the Sun. Therefore, it can be excluded from the GH effect. When the SW flux  
67 is decreased from LW<sub>dn</sub>, the rest of this flux is  $345.6 - 75.0 = 270.6$  Wm<sup>-2</sup>. This flux is called  
68 a GH flux (GH<sub>dn</sub>), because it is the only available extra energy warming the Earth's surface.

69

70 The GH<sub>dn</sub> flux is the sum of three different energy source, which has been already identified  
71 [3] and they are: LW absorption by the GH gases and clouds (155.6 Wm<sup>-2</sup>), latent heating  
72 90.8 Wm<sup>-2</sup>, and sensible heating 24.2 Wm<sup>-2</sup>. Together with the SW absorption flux, these  
73 fluxes summarize exactly the LW<sub>dn</sub> flux value of 345.6 Wm<sup>-2</sup>.

74

76 This approach does not create a physical contradiction that an energy source of  $155.6 \text{ Wm}^{-2}$   
 77 could create an energy flux of  $270.6 \text{ Wm}^{-2}$ , which provides the real extra warming effect on  
 78 the Earth's surface making the GH effect possible.

79  
 80 The percentages of individual GH effect contributors have been calculated by removing one  
 81 factor a time from the atmospheric model and recording the reduction of the total absorption  
 82 value. This is the same method as used by Kiehl and Trenberth [4]. The results are depicted  
 83 in Table 1.

84  
 85 **Table 1.** Greenhouse effects according to individual contributors in all-sky conditions.

LW absorption	All-sky	Contr.-%	°C
Water	90.9	33.6	11.1
Carbon dioxide	20.1	7.4	2.5
Ozone	6.9	2.6	0.8
Methane & Nitrogen oxide	1.8	0.7	0.2
Clouds	35.9	13.3	4.4
LW absorption	155.6		
Latent heating	90.8	33.6	11.1
Sensible heating	24.2	8.9	2.9
GH effect	270.6		

86  
 87 The greatest difference in comparison to the earlier study [3] is the contribution of clouds,  
 88 which is 13.3 % corresponding to  $35.9 \text{ Wm}^{-2}$  of radiation effect. This value is very close to  
 89 the same of Schmidt et al. [5], which is  $38.75 \text{ Wm}^{-2}$ . In percentages, the difference is much  
 90 greater (13.3% versus 25%) because in the latter study latent and sensible heating are not  
 91 included in the total absorption  $\text{GH}_{\text{dn}}$  value. The contribution of  $\text{CO}_2$  is only 7.4%, which is  
 92 insignificantly greater than the earlier value of 7.3% [3].

93  
 94 **3. FITTING THE SIMPLE CLIMATE MODELS INTO THE GREENHOUSE EFFECT**

95  
 96 Ollila has analyzed in the earlier study the effects of the new GH effect definition on the  
 97 climate models. He has used two simple models, which can be used for calculating the  
 98 temperature effect of increased  $\text{CO}_2$  concentration up to the concentration of 1370 ppm  
 99

100 
$$dT = \lambda * k * \ln(C/280) \quad (1)$$

101  
 102 where dT is the global surface temperature change (K) starting from the year 1750,  $\lambda$  is the  
 103 climate sensitivity parameter ( $\text{K}/(\text{Wm}^{-2})$ ) being 0.324 in the IPCC model [5], and 0.27 in the  
 104 Ollila model and k is a parameter being 5.35 in the IPCC model and 3.12 in the Ollila model.  
 105

106 These IPCC model parameters give Transient Climate Sensitivity (TCS) values of  $1.2^\circ\text{C}$  and  
 107  $0.6^\circ\text{C}$  value for the Ollila model. IPCC has reported [6] that the TCS value is  $1.2^\circ\text{C}$  if there  
 108 are no feedbacks included. These two curves have been depicted in Figure 2. The  $\text{CO}_2$   
 109 warming impact curves have been adapted to give a total warming value of  $2.5^\circ\text{C}$  caused  
 110 by the  $\text{CO}_2$  concentration of 400.9 ppm [3]. The warming change from  $\text{CO}_2$  concentration 0

\*  
 E-mail address: aveollila@yahoo.com

111 ppm to 280 ppm (dashed curves) is based on the absorption decrease by spectral  
 112 calculations [3].  
 113

114  
 115 **Figure 2.** Warming effects of CO<sub>2</sub> according to the new greenhouse effect of CO<sub>2</sub> being 2.5  
 116 °C in 2014 (400.9 ppm). CO<sub>2</sub> warming effects from 280 ppm onward are per a green curve,  
 117 TCS = 0.6 °C, and per IPCC (2013), a red curve, TCS = 1.2 °C.

118 The general feature of absorption is that the absorption rate change, i.e. the angle coefficient  
 119 of the absorption curve, diminishes with increasing GH gas concentration. The absorption  
 120 due to a GH gas follows also another general rule of absorption, which is that increasing  
 121 concentration change from zero upward has the strongest effect in the beginning. The  
 122 starting phase approximately follows the Beer-Lambert law, which states that absorbance  
 123 depends linearly on the concentration and path length. When the concentration increases,  
 124 this relationship is no longer valid. There is a very nonlinear dependency from 20 to 100 ppm  
 125 for CO<sub>2</sub>, and thereafter the relationship is slightly nonlinear after 280 ppm, which can be  
 126 approximated by a logarithmic relationship very well.

127  
 128 The curve of the model (TCS = 0.6 °C) according to Eq. (7) of this study shows a smooth  
 129 feature of a warming rate without a transition point at the 280 ppm. The curve of the IPCC  
 130 model (TCS = 1.2 °C) has a transition point at 280 ppm, because the angle coefficient starts  
 131 to increase after 280 ppm, when it should steadily diminish. This curve fitting shows that the  
 132 IPCC model cannot be fitted into this new GH effect magnitude.

134 **4 DISCUSSION**

135  
136 There is quite a lot of confusion if Planck's law is applicable in the troposphere where 98% of  
137 absorption happens and the downward LW radiation to the surface. The IPCC's definition [1]  
138 lets to understand that only GH gases emit infrared radiation but Hartmann [2] writes that the  
139 atmosphere radiates.

140  
141 The surface energy balance value is  $510.6 \text{ Wm}^{-2}$ . There are only two fluxes entering the  
142 surface: the SW flux of  $165 \text{ Wm}^{-2}$  and  $\text{LW}_{\text{dn}}$  of  $365.6 \text{ Wm}^{-2}$ , a totally of  $510.6 \text{ Wm}^{-2}$ . If the  
143  $\text{LW}_{\text{dn}}$  flux would be the same as LW absorbed flux  $155.6 \text{ Wm}^{-2}$  plus the SW absorption of  $75$   
144  $\text{Wm}^{-2}$ , the surface energy fluxes would not be in balance. The energy balance of the  
145 atmosphere shows that the downward LW radiation must include latent and sensible heating  
146 effects because then the surface in and out energy fluxes are perfectly in balance.

147  
148 The GH gases and clouds absorb both LW and SW radiation fluxes and this process  
149 increases the temperature of the atmosphere. Also, latent and sensible heating increases  
150 the atmospheric temperature. The atmosphere emits radiation according to its temperature  
151 as Planck's law dictates. If this would not happen, the  $\text{LW}_{\text{dn}}$  would not be exactly the sum of  
152 these four energy fluxes. The absorption by the GH gases and clouds in the atmosphere has  
153 no special role in maintaining the atmospheric temperature profile. Latent and sensible  
154 heating also maintain this profile even though the heat transfer process is different.

155  
156 It should be noticed that although clouds have clearly positive impact on the GH effect, the  
157 permanently increased cloudiness does not increase the surface temperature. This is due to  
158 the fact that increased cloudiness decreases at the same time the incoming solar radiation  
159 and the net effect is the decrease in the surface temperature.

160  
161 The AGW theory emphasizes the role of  $\text{CO}_2$ . In this theory the contribution of  $\text{CO}_2$  has been  
162 considered higher than its contribution calculated by the method of removing its impact in  
163 spectral calculations. The basis for this increased effect is that the atmosphere, if  $\text{CO}_2$  were  
164 removed from it, would cool and much of water vapor would rain out. This would cause more  
165 raining, and this would cause further cooling resulting even glaciated snowball state [1].

166  
167 A more realistic state of the climate is to think about the situation of climate zones if the  
168  $\text{CO}_2$  concentration would be zero. The total absorption in the tropics would be only 2.2 %  
169 smaller having an insignificant impact on the surface temperature. The surface temperature  
170 of the polar summer is the same as the average global climate and the reduction of the total  
171 absorption would the same as the global average temperature ( $2.5 \text{ }^\circ\text{C}$ ). Although the  
172 absolute water amount would decrease, it would not be enough to cause a glaciation of the  
173 Earth.

174  
175 **5 CONCLUSION**

176  
177 The first conclusion of this study is that the GH effect definitions should be changed to be  
178 like this: "*The Earth's surface emits LW radiation (infrared radiation) and it transfers heat*  
179 *energy in the form of latent and sensible heating into the atmosphere. Most of the emitted*  
180 *infrared radiation is absorbed by trace gases and clouds in the atmosphere. All three energy*  
181 *fluxes increase the temperature of the atmosphere. The part of the infrared radiation due to*  
182 *these three energy sources emitted downward from the atmosphere adds to the warming of*  
183 *Earth's surface by sunlight and it is called the greenhouse effect.*"  
184

\*

E-mail address: aveollila@yahoo.com

185 **The second** conclusion is the warming effects of the increasing carbon dioxide concentration  
186 according to the IPCC's applied models cannot be fitted into the total magnitude of the CO<sub>2</sub>  
187 contribution for the GH effect.
