13 **ABSTRACT**
14

This study was conducted to analyse profitability of HYV Boro during the 2016 Boro season. BR-29 variety was selected for analysis as this variety is dominated among all Boro varieties in the study area. A total of 75 farmers were randomly selected from seven villages of Islampur Upazilla under Jamalpur district who produced BR-29 boro variety. Primary data were collected from the selected farmers. Cost and return analysis as well as functional analysis were performed in this study. Cobb-Douglas production function was also used to determine the effects of individual inputs on production of BR-29. Human labor, land cultivation, seed, fertilizer, manure, irrigation and pesticides were seven variables used. It was observed from the result that most of the included variables had significant impact on BR-29 Boro production. This study also identified some problems faced by the farmers in producing BR-29 Boro rice. These were low price of output, scarcity and high wage rate of human labour, high irrigation cost, Lack of credit facilities etc. Therefore, more research and extension is suggested to solve the farmer's problems in order to increase production of Boro rice and to ensure food security in Bangladesh.

18
19 **1. INTRODUCTION**
20

21 Bangladesh is a developing country with an estimated 2019 population of nearly 168.07 million in an area
22 of 147,570 square kilometers. The density of population is the highest (1,115.62/square kilometer) in the
23 world (World Population Review, 2019). Bangladesh is mainly an agricultural country and its economy is
24 substantially agro based. Agriculture is the well-recognized driving force of the economy of Bangladesh.
25 The importance of agriculture, especially the crop sector, to the economy of Bangladesh needs no
26 emphasizing. There are three types of rice namely Aus, Aman and Boro covering 1.15, 5.51 and 4.68
27 million hectares of land in Bangladesh respectively (Mia, 2009). Rice is the staple food of 155.8 million
28 people in Bangladesh (BER, 2015); it supplies 69.8% of the total caloric intake and more than 58% of the
29 protein intake (FAO, 2015). Rice production is the largest contributor to farm income, while related trade
30 and commerce are important sources of rural non-farm income (Ahmed, 2001). Bangladesh is the fourth
31 largest rice producer in the world (FAO, 2010).

32 In the past, the country was largely dependent on importation of food grains with its deficit production.
33 This was due to pressure of increasing population. But in recent years a remarkable change in rice
34 production has already been observed in Bangladesh after introducing of HYV varieties of rice which has
35 made remarkable progress in achieving its food security. Bangladesh Rice Research Institute (BRR1) has
36 developed and released 46 Modern Varieties (MVS) having potential to produce 2.0 or more times yield

37 than those of traditional varieties. Among the varieties Boro HYV BRRI dhan 29, released in 1994 has
38 high performance in respect of yield, quality, insect and disease resistance and this Boro rice grown
39 during November to February where seedling are raised in a seedbed and transplanted in the main field
40 (Islam, 2007). The variety is Moderately resistance to leaf blight, sheath blight and has an average yield
41 of 7.5 ton/ha (BRRI, 2019).

42 Boro is the common rice crop in Bangladesh. Structural change in input and output prices of rice in
43 Bangladesh and more dependence on Boro season has made rice production a function of input supply
44 and prices of both inputs and outputs rather than vagaries of nature. As Boro is the main rice crop in
45 Bangladesh, stability of farm income is largely dependent on profitability from Boro production. Therefore,
46 main focus of this study is to analyse profitability of Boro production in 2016 season.

47 The objectives of this study is to analyze profitability of BR-29 in 2016 Boro season, to identify major
48 problems faced by BR-29 producing farmer and to suggest some recommendations for policy makers.

49 **2. METHODOLOGY**

50
51
52 Researchers follow a set of tools and techniques in order to fulfill the aims and objectives of the study.
53 Researchers further try to find unbiased results of their studies within limited time, money and personnel.
54 Farm management research by its very nature essentially involves primary data collected from the
55 farmers. The type of primary data to be collected depends upon the nature of the study and its objectives.
56 The present study was based on a field survey where primary data were collected from BR-29 growers.
57 Methodology mainly covers selection of the study area, selection of the samples, preparation of the
58 survey questionnaire, and collection of the data, tabulation, analysis and interpretation of the data.

59 **2.1 Study Area**

60
61
62 Islampur Upazila, located in between 24°57' and 25°10' north latitudes and in between 89°38' and 89°56'
63 east longitudes covers an area of 343.02 sq km (Islam, 2015). Average temperature of this area ranges
64 from 10.8° C to 22.2° C. The average rainfall of this site is recorded 2153 ML. Its average humidity is
65 79.3% (BBS 2013).

66 **2.2 Sampling Technique**

67
68
69 It was impossible to interview all the BR-29 growers in the study area due to limitations of time and
70 resources. Considering time, availability of fund and manpower, a limited number of farmers were
71 selected randomly. For sampling, at first a list of BR-29 growers in a village was prepared. From a list of
72 farmers of a village, 10-12 farmers were randomly selected. Thus, 75 farmers were selected from the
73 randomly selected seven villages of Islampur Upazilla of Jamalpur district. Profitability of any enterprise
74 varies due to managerial capacities of different farmers. To control the management factor, farmers who
75 produced BR-29 in 2016 Boro season were chosen for this study.

76 **2.3 Analytical Technique**

77
78
79 In the present study the statistical techniques were also used to supplement the tabular technique. Simple
80 descriptive statistics like frequency, arithmetic mean, percentages and ratios were used and interpretation
81 and discussion of the findings were presented in simple terms.

82 **Cobb-Douglas production function**

83
84
85 Cobb-Douglas production function model was also used to identify the effect of key factors on production
of BR-29.

86 The analysis was done for the production of BR-29 in 2016 Boro season. The specification of the Cobb-
87 Douglas production function is as follows;

88
89 $Y = a X_1^{b_1} X_2^{b_2} X_3^{b_3} X_4^{b_4} X_5^{b_5} X_6^{b_6} X_7^{b_7} e^{u_i}$

90
91 In the linear form it can be written as follows:

92
93 $\ln Y = \ln a + b_1 \ln X_1 + b_2 \ln X_2 + b_3 \ln X_3 + b_4 \ln X_4 + b_5 \ln X_5 + b_6 \ln X_6 + b_7 \ln X_7 + \dots + U_i$

94
95 Where,

96
97 Y= Gross return of BR-29 Boro rice production (Tk/acre)

98 a= Constant or intercept

99 X_1 = Cost of human labour (Tk/acre)

100 X_2 = Cost of land cultivation (Tk/acre)

101 X_3 = Cost of seed (Tk/acre)

102 X_4 = Cost of fertilizer (Tk/acre)

103 X_5 = Cost of manure (Tk/acre)

104 X_6 = Cost of irrigation (Tk/acre)

105 X_7 = Cost of pesticide (Tk/acre)

106 ln= Natural logarithm

107 $b_1, b_2 \dots b_7$ are co-efficient of respective variables

108

109 **Gross return (GR)**

110

111 Gross return was calculated by multiplying the total volume of output of an enterprise by the average
112 price in the harvesting period. The following equation was used to estimate GR.

113
114 $GR_i = \sum_{i=1}^n Q_i P_i$

117 Where,

118 GR_i = Gross return from ith product (Tk/acre);

119 Q_i = Quantity of the ith product (kg/acre);

120 P_i = Average price of the ith product (Tk/kg); and $i = 1, 2, 3 \dots n$.

121

122 **Net return (NR)**

123

124 Net return analysis considered fixed costs; cost of land rent, interest on operating capital etc. Net return
125 was calculated by deducting all costs (variable and fixed) from gross return. To determine the net return
126 of BR-29 Boro production, the following equation was used in the present study:

127

128 $NR = GR - TC$

129

130 NR= Net return (Tk. /hectare)

131 GR = Gross return (Tk./hectare); and

132 TC = Total cost (Tk./hectare) In this study, cost and return analysis was done on both variable and total
133 basis.

134 The following profit equation was developed to assess the profitability of fish production:

135 $\pi = \text{Gross return} - (\text{Variable cost} + \text{Fixed cost})$

136

137 Here, π = Profit per hectare;

138

139

140

141

Benefit-Cost Ratio (BCR)

The benefit cost ratio (BCR) is a relative measure which is used to compare benefit per unit of cost. BCR was estimated as a ratio of gross return and gross costs. The formula of calculating BCR (undiscounted) is shown as below:

$$BCR = \frac{\text{Gross Benefit}}{\text{Gross Cost}}$$

- If a project has a BCR greater than 1.0, the project is expected to deliver a positive net present value to a firm and its investors.
- If a project's BCR is less than 1.0, the project's costs outweigh the benefits and it should not be considered.

3. RESULTS AND DISCUSSION

3.1 Profitability Analysis

This section mainly deals with the pricing procedures for items of costs and returns of BR-29 Boro production. In calculating profit or loss of an enterprise or relative profitability of different crops costing of inputs and valuation of output is essential. Farmers in the study area used both purchased and home supplied inputs for the production of BR-29 Boro rice, which were valued at the prevailing market rate during survey period or at the price paid by the farmers. The output was also valued at the prevailing market price. Purchased input such as seed, fertilizer, irrigation, pesticides, hired labour etc. involved direct expenses and therefore, pricing of these inputs was easy. Since no cash payment was made for the home supplied inputs, the costs of these inputs were estimated by using the opportunity cost principle. For analytical advantage, the cost items were classified under the following headings: human labour, animal labour, power tiller, seed, fertilizer, manure, pesticides, irrigation, land use cost and interest on operating capital.

Table 1. Per acre cost and returns of BR-29 in the study area

Particulars	Unit	Results
Gross Cost (GC)	Tk.	45875.00
Main product (paddy)	kg.	3000.00
Per unit price of paddy	Tk./kg	16.00
Value of product	Tk.	48000.00
Value of by- product	Tk.	8750.00
Gross Return (GR)	Tk.	56750.00
Net Return (NR)	Tk.	10875.00
Benefit Cost Ratio (BCR)	-	1.23

Source: Field Survey, 2016

Table 1 shows that average yield of BR-29 in Jamalpur district was 3000 kg./acre. The gross returns (including by product) from BR-29 were estimated Tk. 56750.00. The average net returns per acre was found to be Tk. 10875.00 for BR-29.

On the basis of gross costs per hectare, production cost of BR-29 was estimated at Tk. 45875.00. Results in Table 1 shows that BCR of BR-29 rice production showed 1.23 that Tk 1.23 would be earned by spending each Tk 1.00 investing in the rice production. So, it is clear that BR-29 rice production is profitable in the study area.

186 **Factors affecting gross return of selected rice production**

187
188 To determine the effects of the explanatory variables, linear and Cobb-Douglas model were initially
189 estimated for BR-29 rice production. Some of the key variables are explained below.

190
191 Human labor cost (X_1): The coefficient for human labor cost was 0.410 which was positive and significant
192 at five percent level of significance. The coefficient indicates that keeping other factors constant, 1
193 percent increase in human labor cost would increase the gross return by 0.337 percent (Table 2).

194
195 Land cultivation cost (X_2): The regression coefficient for land cultivation cost was positive at five percent
196 level of significance (Table 2). It revealed that 1 percent increase in the land cultivation cost, holding other
197 factors constant would increase gross return by 0.333 percent.

198
199 Seed cost (X_3): The regression coefficient of seed cost was positive for BR-29 rice and significant at five
200 percent levels. It indicated that 1 percent increase in seed cost, keeping other factors constant would
201 increase gross returns by 0.554 (Table 2).

202
203 Fertilizer cost (X_4): For BR-29, the coefficient was positive and significant at one percent levels of
204 significance which indicated that 1 percent increase in the cost of fertilizer, keeping other factors constant,
205 would increase gross return by 0.061 percent (Table 2).

206
207 Manure cost (X_5): Regression coefficient of manure cost was found to be positive and statistically
208 insignificant. It indicated that 1 percent increase in manure cost, keeping other factors constant would
209 increase gross returns by 0.010 percent (Table 2).

210
211 Irrigation cost (X_6): Regression coefficient of irrigation cost was found to be negative and statistically
212 insignificant. It indicated that 1 percent increase in irrigation cost, keeping other factors constant would
213 decrease gross returns by 0.345 percent (Table 2).

214
215 Pesticides cost (X_7): For BR-29 rice, the coefficient was negative and statistically significant at 1% level. It
216 implies that 1 percent increase in the cost of pesticide, holding other factors constant, would decrease
217 gross return by 0.047 percent for BR-29 rice (Table 2).

218
219 The coefficients of multiple determinations, R^2 value of the model was 0.976 indicating that about 97.6
220 percent of variations in gross return have been explained by the explanatory variables, which were
221 included in the model. The value of adjusted R^2 was 0.974 indicating that after taking into account the
222 degrees of freedom (df) adjusted R^2 , explanatory variables in the model still explain about 97.4 percent of
223 the total variations in gross returns from BR-29 (Table 2).

224
225 The F-values of the equation derived for BR-29 was 393.67 implying that all the explanatory variables
226 were important for explaining the variations in gross returns of BR-29 in the study area (Table 2).

227
228 The summation of all the regression coefficients of the estimated production functions of BR-29 was 0.98
229 found to be less than 1 which indicated that the selected rice growers allocated their resources in the
230 rational stage of production (Stage II) respectively, where diminishing returns to scale exists.

 246

247 3.2 Problems and constraints of BR-29 Boro production

248
 249 Farmers faced a lot of problems and constrains in producing BR-29 Boro rice. In the present study, an
 250 effort has been made to identify and analyze the major problems and constraints faced by the farmers in
 251 producing BR-29 Boro rice in the study area. Some major problems and constraints which the farmers
 252 emphasized upon are discussed below:
 253

254 **Table 32.** Problems faced by BR-29 growers
 255

Problems and Constraints	Number of farmers	% of total farmers
i. Low output price	70	93
ii. Scarcity of human labour	60	80
iii. High irrigation cost	52	69
iv. Load shading of electricity	40	53
v. Scarcity of animal labour	44	58
vi. Lack of capital	45	60
vii. Lack of manure	45	40

256 Source: Field Survey, 2016
 257

258 4. CONCLUSION AND RECOMMENDATIONS

259
 260 BR-29 Boro production in Islampur upazila of Jamalpur district is found to be profitable. Though BR-29
 261 provides more benefits to the farmers, they were facing some problems which need attention from
 262 government. On the basis of the findings of the study the following recommendations are made for the
 263 improvement of existing BR-29 Boro rice production.
 264

- 265 i. The policy makers should think to introduce agricultural mechanization in the study area.
- 266 ii. During the harvest time farmers get very low prices for their product so proper price should be ensured
 267 in harvesting time.
- 268 iii. There is a price support programme for paddy in this country. It must be implemented effectively during
 269 the harvesting period of paddy.
- 270 iv. Credit facility should be provided to the farmers for applying recommended doses of seed, fertilizer,
 271 irrigation etc. So that yield of BR-29 Boro rice can be increased.

272 v. Extension services and its linkage with farmers should be improved to make available knowledge to the
273 farmers.
274
